## GLOSSARY

Pedagogical Agents: 2D or 3D animated characters that are developed to be utilized in a digital educational environment. They are used to supplement and enhance lectures or interactive lessons.

Gesture: A pose that an APA may perform to either express an emotion or to provide body language that helps to facilitate learning.

Syncing: Refers to the process of timing animations or other time sensitive elements (i.e. a Slideshow), especially to an audio source.

Animation Clips: A development technique where actions (i.e. Walking, Pointing) are all stored in a prebuilt database of clips. The resulting animation is then constructed by combining and interpolating between the clips. Some animation clips can be looped seamlessly.

Valence: Refers to a character's mood when expressing an emotion. High valence means that the character is in a pleasant (i.e. happy) mood, while low valence means that the character is in an unpleasant (i.e. sad or angry) mood.

Arousal: Refers to a character's level of energy when expressing an emotion. High arousal means the character has a high level of energy (i.e. excitement or anger), and low arousal means that the character has a low level of energy (i.e. sad or calm).

ABSTRACT<br>Author: Cheng, Justin, D. Institution: Purdue University<br>Degree Received: December 2019<br>Title: Determining if Modifying an Animated Pedagogical Agent's Body Gesture and Gender Affects Human Emotional Perception<br>Committee Chair: Nicoletta Adamo-Villani

The goal of this research is to develop Animated Pedagogical Agents (APA) that can convey clearly perceivable emotions through speech, facial expressions and body gestures. In particular, the two studies reported in the thesis investigated the extent to which modifications to the range of movement of 3 beat gestures, e.g., both arms synchronous outward gesture, both arms synchronous forward gesture, and upper body lean, and the agent 's gender have significant effects on viewer's perception of the agent's emotion in terms of valence and arousal. For each gesture the range of movement was varied at 2 discrete levels. The stimuli of the studies were 812 -seconds animation clips generated using a fractional factorial design; in each clip an animated agent who speaks and gestures, gives a lecture segment on binomial probability. 4 clips featured a female agent and 4 clips featured a male agent. In the first study, which used a withinsubject design and metric conjoint analysis, 120 subjects were asked to watch the 8 stimuli clips and rank them according to perceived valence and arousal (from highest to lowest). In the second study, which used a between-subject design, 300 participants were assigned to two groups of 150 subjects each. One group watched the 4 clips featuring the male agent and one group watched the 4 clips featuring the female agent. Each participant was asked to rate perceived valence and arousal for each clip using a 7-point Likert scale. Results indicated that extending the arms outwards and forwards as well as modifying the agent's gender from male to female increased perceived valence and arousal, whereas rotating the body backwards increased only perceived valence.

## CHAPTER 1. INTRODUCTION

### 1.1 Problem Statement

A current challenge is the process of effectively teaching material through distance learning. One novel approach is using pedagogical agents, which are virtual animated characters embedded in e-learning environments. Research has shown that animated pedagogical agents (APA) can be effective in promoting learning (Schroeder, Adesope, \& Gilbert, 2013), but many questions remain unanswered, particularly concerning their emotional design. With the growing understanding of the complex interplay between emotions and cognition, there is a need to develop life-like agents that not only provide effective expert guidance, but also convincing emotional interactions with the learner (Yanghee Kim \& Baylor, 2016).

There has been considerable debate as to whether posture and movement reliably convey emotions, or rather convey only the intensity of the emotion (Ekman \& Friesen, 1969; Lhommet \& Marsella, 2015). We examine how body gestures might convey both the quality of the emotion and its level of activation. We use Russell's (2003) model of core affect in which any particular emotion can be placed along two dimensions, valence (ranging from positive to negative), and arousal (ranging from activation to deactivation) and investigate whether and how changes in the motion parameters of a set of body gestures affect the perception of the agent's emotion along both dimensions. We also examine whether the agent's gender has an effect on viewer's perception of the emotional content.

Studies like the ones reported in this thesis are important because they may advance not only research on representation of emotion in affective embodied agents, but also psychology research on bodily expression/perception of emotion in general.

### 1.2 Purpose

The purpose of this research is to develop APAs that can convey clearly perceivable emotions through speech, facial expressions and body gestures. The studies
reported in the thesis are a first step in this direction. They focus on how emotions are conveyed through body cues and, in particular, they examine the extent to which modifications to the range of movement of a set of beat gestures affects viewer's perception of the agent's emotional state. An important issue in bodily expression of emotion research concerns the distinction between a person's encoding of emotion in physical behavior versus an observer's decoding of emotion from observations of the person's behavior. We are concerned with the latter, and whether the observed perceptual effects are moderated by viewer's characteristics such as gender, age, and educational level.

### 1.3 Assumptions

This research used the following assumptions:

- Study participants were honest with their opinion throughout the procedure. They were to answer the survey based on their own knowledge and experience, rather than answering based on what they assumed the researchers would like to observe. The study participant's intent was that they were interested to contribute towards the study.

### 1.4 Limitations

This research acknowledged the following limitations:

- The agent's gesture modifications were performed by a parameterized script rather than by manual keyframing. This potentially meant there may be occasional postures in the animation that might not be perceived as natural.
- Participants needed to be able to identify different emotions through only a few changes in visual body cues.
- Even though the agents within the study had both a blurred face and young adult proportions, their intrinsic design characteristics could initially influence emotional perception.
- Perception of the agent's emotional state might have been influenced by the differences between the male and female voice recordings used in the clips.

### 1.5 Delimitations

This research acknowledged the following delimitations:

- The topic used in the study's digital lecture was from statistics.
- Animations used in the study were assembled using interpolated pre-built motioncaptured animation clips rather than manual keyframe animation to save time during production.

### 1.6 Definitions

The following key definitions are used throughout this paper:

- Valence: the perceived positivity from a character's body language, ranging from unpleasant (low valence) to pleasant (high valence)
- Arousal: the perceived energy level from a character's body language, ranging from deactivated / disengaged (low arousal) to activated / engaged (high arousal)

### 1.7 Abbreviations

The following abbreviations are used throughout this paper:

- $O G$ : Short for open gesture, used when referring to spreading the arms horizontally in relationship towards the agent's body.
- FG: Short for forward gesture, used when referring to spreading the hands directly in front of the agent's body.
- BL: Short for body lean, used when referring to the forward or backward tilt of the agent's upper torso.
- $G$ : Short for the gender parameter
- $O G x F G$ : Represents the interaction when both OG and FG are adjusted simultaneously
- OGxBL: Represents the interaction when both OG and BL are adjusted simultaneously
- FGxBL: Represents the interaction when both FG and BL are adjusted simultaneously

## CHAPTER 2. LITERATURE REVIEW

In this section, first, I examine prior research on the benefits of including animated agents in digital media learning. Second, I discuss expression of emotions through body gestures and report different classifications of emotions, especially Russell's Model of Affect. Third, I review prior studies on perception of agents' emotions from body cues, as well as prior studies based on the perception of the agents' gender.

### 2.1 Affective Pedagogical Agents

Studies have suggested that the presence of pedagogical agents improves learning. A meta-analysis by Schroeder suggested that lessons with animated pedagogical agents displayed a statistically significant learning improvement compared to lessons without them (Schroeder et al., 2013). One characteristic of why a pedagogical agent helps to facilitate learning was that they could "signal the learner's attention to the relevant information" (Schroeder et al., 2013). A test performed by Wang suggested that having a pedagogical agent point to diagrams on display helped to redirect the viewer's eye gaze on the subject matter (Wang, Li, Mayer, \& Liu, 2018). This consequently led to students that had a lecture with gesturing agent score higher on a post-lesson test than students that had a lecture with a static agent or without an agent.

Another reason why pedagogical agents help to facilitate learning could be that the viewers find them engaging because of their "human-like" personalities (Dehn \& Van Mulken, 2000, p. 2). A study by Poggiali showed that students found "animated videos easier to learn form, in part because they held their attention" (Poggiali, 2018, p. 36). The agent's personality helped to contribute towards the student's engagement; study participants reported that the agent's outgoing personality helped them relate to it like an outgoing human instructor. This emphasizes the importance of establishing a social connection between the agent and the learner.

Despite the positive benefits of utilizing pedagogical agents, the agent could be a visual distraction if its presence does not contribute towards presenting on-screen
information. The cognitive load theory suggests that the presence of pedagogical agents may contribute to additional cognitive load (Clark \& Choi, 2007). Wang's study has shown that study participants that had a static non-gesturing pedagogical agent in a lesson scored just about as poorly as the participants that did not have a pedagogical agent (Wang et al., 2018, pp. 259-260). The eye-tracking information demonstrated that for both the static agent and the animated agent, the amount of time spent gazing at the agent was roughly the same. The key difference was that the animated agent constantly pointed to course material, whereas the static agent was primarily a bystander that was not integrated into the lesson. In short, the animated agent helped the viewers to redirect their eyes back towards the slideshow (Wang et al., 2018).

### 2.2 Expression of Emotions through Body Gestures

The agent's gestures are crucial in conveying its emotional state, as non-verbal cues potentially can make up to $93 \%$ of the conversation during conversation (Larsson, 2014, pp. 6-7). A study by Anasingaraju showed that body motion was the biggest contribution to a believable stylized animated character, rather than the character's facial and lip sync (Anasingaraju, 2017). Incorporating emotional design within the pedagogical agents improved learning outcomes within a lesson (Mayer \& Estrella, 2014), showcasing the need for the agents to have recognizable emotions.

An emotion, or an affective state, is a short duration-mood that is closely associated towards a specific event (André, Klesen, Gebhard, Allen, \& Rist, 2000). Ekman classified emotions in six basic categories. e.g. happiness, sadness, anger, disgust, fear, and surprise (Ekman, 1992). A study by Atkinson has shown that viewers were able to recognize five of the six basic emotions (Surprise was not tested in the study) from static and dynamic images containing body markers (Atkinson, Dittrich, Gemmell, \& Young, 2004). A similar study by Coulson using a posed virtual mannequin confirmed the similar results (Coulson, 2004).

Despite gestures playing a crucial role in conversation, identifying emotions from body gestures alone is not straightforward. Several emotions are easily classifiable through body gestures only, especially basic emotions such as anger, sadness, and
happiness (Karg et al., 2013). However, there are also emotions that are difficult to express with body language alone. From Ekman's basic emotions, surprise, disgust, and fear are the most difficult emotions to express from arm movements alone (Sawada, Suda, \& Ishii, 2003). A study by Atkinson suggests that sadness and disgust were most easily misclassified for each other (Atkinson et al., 2004). A study by Ennis showed that body gestures only without the face caused confusion in differentiating emotions with high arousal (Ennis, Hoyet, Egges, \& McDonnell, 2013). Ennis concluded that body gestures alone caused difficulties in identifying between happy and angry gestures, but in contrast sadness and fear were more identifiable from each other. Karg has also stated that high valence and low arousal gestures, such as content, were not easy to express from gestures alone (Karg et al., 2013). While gestures may help to differentiate between emotions with high and low valence, arousal was more easily identifiable by agent's movement than just from still poses. This helped to forewarn that there was a possibility that showing off one emotion's gestures could result in a misclassification of another emotion with similar arousal levels.

### 2.3 Russell's Model of Affect

Russell's Model of Affect (RMA) classifies most human emotions along two dimensions: valence (ranging from displeasure to pleasure) and arousal ranging from deactivation to activation) (Russell, 2003). Figure 2.1 shows a diagram of RMA, where valence and arousal form two axes of the model. Combinations of positive or negative valence and arousal can lead to the emotion being placed in quadrant 1 (anger and confusion), quadrant 2 (happiness), quadrant 3 (content), and quadrant 4 (sad and tired).

Figure 2.1: Russell's Model of Affect. (Russell, 2003)

### 2.4 Gestures and Perception of Agents' Personality

Compared to an emotion, a personality is defined as a set of permanent or longlasting complex characteristics that make up how the agent interacts with the environment (André et al., 2000). In this section I review primarily studies that compared between extroverted and introverted personalities. Table 2.1 sums up the gestural and movement difference between introversion and extraversion based on Neff's study findings.

Table 2.1: Introversion and Extraversion difference table

|  | Introversion | Extraversion |
| :--- | :--- | :--- |
| Body Attitude | Backward learning, turning <br> away | Forward leaning |
| Gesture Amplitude | Narrow | Wide, broad |
| Gesture Direction | Inward, self-contact | Outward, table-plane and <br> horizontal spreading <br> gesture |
| Gesture Rate | Low | High, more movement of <br> head, hands, and legs |
| Gesture Speed, <br> Response time | Slow | Fast, quick |
| Gesture Connection | Low smoothness, rhythm <br> disturbance | Smooth, fluent |
| Body Part | Legs leaning, bouncing, <br> shaking of legs | Head tilt, shoulder erect, <br> chest forward, limbs <br> spread, elbows away from <br> body, hands away from <br> body, legs apart |

Note. Adapted from Neff (2010)

An agent with an extroverted personality is more likely to show interest and friendliness towards the viewer (Allbeck \& Badler, 2002; Mehrabian, 1996). In order to look more engaged, the agent tends to open outwards to amplify a sense of space, (Neff et al., 2010), such as extending the hands horizontally, rotating out the elbows, and raising the shoulders. An agent that expresses friendliness, tends to consistently make eye contact with the viewer (Neff et al., 2010) and open up the arms towards the viewer (Ball \& Breese, 2006). In general, an extroverted agent is likely to express emotions that have positive valence and high arousal.

An agent with an introverted personality tends to show disinterest towards the viewer. As a result, the agent is more likely to focus on minimizing their body size (André et al., 2000). The upper torso is more likely to stand upright or to lean slightly backwards, whereas the hands are prone to close and touch the agent's own body (Neff et al., 2010). When comparing the horizontal spread the agent's gestures, the introverted agent's horizontal spread is only $10 \%$ to $60 \%$ of the extroverted agent's horizontal spread (Neff et al., 2010). Considering that the introverted agent is more prone to minimizing occupied space, the agent tends to perform fewer out-directing gestures, leading to the introverted character showing more submissiveness (Allbeck \& Badler, 2002). Looking at the attributes listed above, this means that an introverted agent is more likely to show emotions that have negative valence and low arousal.

The relationship between valence, arousal, and personality is better illustrated by the Positive and Negative Affect Schedule (PANAS) included in Figure 2.3 (Watson, Clark, \& Tellegen, 1988). Extraversion corresponds to having high valence and high arousal, and Introversion corresponds to having negative valence and low arousal. Neuroticism (negative valence and high arousal) and Constructive Thinking (low arousal and positive valence) make up the remaining quadrants.

Figure 2.2: Showing personalities in the PANAS model. (Saerbeck \& Bartneck, 2010)

Extroverted and introverted characters would also show a different amount of control over another person. The Pleasure-Arousal-Dominance (PAD) model was built similarly to RMA, but include an additional dimension, e.g. dominance (third axis) (Mehrabian, 1996). In the PAD-model, dominance is defined as the amount of control that a character had over others (André et al., 2000). An extroverted character asserted more dominance than an introverted character. This gives the extroverted character an additional incentive to both directly make eye-contact towards the viewer and to amplify a larger sense of space (Neff et al., 2010).

While gesture frequency rate and movement speed are not variables that are to be explicitly tested within this study, they both are also factors in identifying personalities. In terms of frequency, an extroverted would perform more gestures than an introverted character in the same time frame (Neff et al., 2010). Considering that an extroverted character is prone to talk more quickly, he would need to provide more conversational gestures to compensate. As for movement speed, an extroverted character's motions are quicker and snappier compared to an introverted character's motion, which are slower and more lethargic (Neff et al., 2010).

### 2.5 Agent's Gender

The gender of the pedagogical agents has shown to affect interaction with the viewers. Some studies suggest that female agents are perceived as more supportive. A study by Baylor and Kim has shown that study participants who have worked with female agents "showed higher self-efficacy beliefs than [study participants] who worked with male agents" (Baylor \& Kim, 2010). However, Baylor and Kim have also conducted an earlier study where study participants who worked with male agents, regardless of the participants gender, were more engaged and showed higher interest in a given exercise (Y. Kim, Baylor, \& Shen, 2007), which was also consistent with past studies indicating that college students "showed higher motivation and more positive perceptions of agents after they had worked with a male agent than after they had worked with a female agent" (Y. Kim et al., 2007).

The gender of the viewer could also influence the interaction with the pedagogical agent. A study by Krämer et al. has shown that a study participants group who interacted with agents that were of the opposite gender resulted in them giving a higher rapport rating that study participants group who interacted with agents with the same gender. This led to the former group having higher learning efforts during the study (Krämer et al., 2016). Baylor and Kim have stated from their results that while both male and female participants rated the male agent as more engaging when the agents were both expressing a positive emotion, study participants were more likely to rate the opposite-gender agent as more engaging when both genders were displaying more negative emotions (Y. Kim et al., 2007).

### 2.6 Summary

The literature review begins with establishing the context behind the motivation of including of pedagogical agents within distance-based online learning materials, as well as the context of emotion classification. Russell's model of affection would serve as basis to quantify emotions with both valence and arousal (Russell, 2003), which would be used throughout the study.

Next, the literature review provides the foundation on body gesture patterns that make up an engaging pedagogical agent. For an agent to appear engaging towards the viewers, the agent would need to expressive traits from an extroverted personality in order to portray friendliness with the viewer. This meant that the agent needed to amplify a larger sense of space and to reach and open out to the viewers more via its arms and upper body (Ball \& Breese, 2006; Neff et al., 2010). Consequently, having the agent minimize space and amplifying distance towards the viewer would result in an agent looking more disinterested in the viewer (André et al., 2000; Neff et al., 2010).

Finally, the literature review investigates on how the pedagogical agent's gender may affect the resulting perceived emotions. Overall, female agents appeared more supportive (Baylor \& Kim, 2010). As for which gender looked more engaging, there have been studies that suggested that either male agents were generally viewed as more engaging (Y. Kim et al., 2007), or that the gender of the participant mattered and that the agent with the gender opposite from the participant was viewed to be more engaging (Y. Kim et al., 2007; Krämer et al., 2016).

## CHAPTER 3. METHODOLOGY

The objective of the studies was to examine the extent to which changes to the range of movement of 3 beat gestures and the agent gender affect viewers' perception of the agent's emotional state along Russell's dimensions of valence and arousal. The three beat gestures selected for the study, e.g., both arms synchronous outward gesture, both arms synchronous forward gesture, and upper body lean, are gestures that are commonly produced by instructors while lecturing and have been shown to convey some information about the speaker's emotional state, personality or status (Cui, AdamoVillani, \& Popescu, 2014).

Two experiments were conducted; one study used a within-subjects design and Metric conjoint analysis; the other study used a between-subject design and linear regression. The stimuli for both studies were 812 seconds clips generated using a partial factorial design, each clip showed a different combination of body gestures and ranges of motion. 150 subjects participated in the first study and 300 subjects participated in the second one. In the first study subjects were asked to watch the stimuli clips and rank them from highest to lowest arousal and valence. In the second study subjects were asked to watch the same stimuli clips and rate the valence and arousal of each clip using a 7point Likert scale.

### 3.1 STUDY 1

### 3.1.1 Defining the Variables.

The study included four independent variables, each one with two levels (see table 3.1 and figure 3.1), and two dependent variables, e.g. valence ranking and arousal ranking of the stimuli clip, with 1 being the highest ranking and 8 being the lowest.

Table 3.1: Representing different factor levels.

| Factor | Level 1 | Level 2 |
| :--- | :--- | :--- |
| OG | Hands are close to body on the sides | Hands are spread apart horizontally |
| FG | Hands are right in front of the body | Hands are stretched in front of the <br> agent |
| BL | Body leans backwards | Body leans forwards |
| G | Agent is Male | Agent is Female |

Figure 3.1: Showing different factor and level changes

While the main factor effects might have been potentially important on their own, there was a possibility that a combination of factors would also be significant. For example, extending the arm/hand outward and forward independently might not result in a significant difference on the participant's valence perception but having a combination of the scenarios might. The two-way effect factors were built from all body gesture factors (OG, FG, and BL). This meant there would be three more parameters that would be considered during statistical analysis: OG and FG (OGxFG), OG and BL (OGxBL), FG and BL (FGxBL).

### 3.1.2 Stimuli

The stimuli were eight 12 -seconds animation clips; in each clip an animated agent who speaks and gestures, gave a lecture segment on binomial probability. Four clips featured a female agent and four clips feature a male agent. All animation clips were assembled within the Unity game engine. The scene, based on a university classroom, included a pedagogical agent and a virtual display. All the gesture animations and slide timings were manually synced using the Unity's Timeline feature.

The full quote that the agent spoke was the following: "A success is defined by you as one or more of the possible outcomes. For example, a success of rolling a die could be that you rolled a number greater than four." The first sentenced served to introduce the concept to the viewer. While the agent was speaking the first sentence, he or she would point towards the viewer with his or her left hand, and then returned to a standing position after the sentence was finished. This gesture was not modified and remained the same in all animation clips. While the agent was presenting a fact with the second sentence, the agent would smoothly transition to another gesture which involved the agent opening out his or her hands and leaning his or her body. This gesture was what altered for all clips. Afterwards, the agent smoothly transitioned back to a standing posture.

The agent in the study was framed from thigh-up, at a $3 / 4$ views towards the camera to more clearly see varying FG and BL levels. Observing body language required the
viewers to view multiple body parts together as a whole, especially the person's head, posture, gestures, and hand positions (Larsson, 2014, pp. 6-7). Identifying an emotion from a body posture is easier if the agent is looking towards the perceiver, as this implies an interpersonal connection between the agent and the viewer (Coulson, 2004).

Figure 3.2: Animation scene layout with female agent

The pedagogical agents were modified from the free Luna Rig provided by Aiden Dendra (Dendra, 2019) for the female agent and from the free Malcolm Rig provided by AnimSchool for the male agent. While the original meshes were used, the skeletal rigs were entirely rebuilt in Autodesk Maya to allow for rig compatibility within the Unity engine. RootMotion's Final IK Unity script was then attached to the agent to allow joint offset adjustments (RootMotion, n.d.). To prevent facial features and facial expressions from being potential confounding variables, the agent's faces were blurred out.

Gesture modifications during the animation were performed by adjusting the joint offset parameters. Figure 3.3 shows the joint local axes that are affected by the offsets. Gesture openness was altered by increasing the horizontal X-axis hand joint offset (red) that is applied to the original animation, with a smaller increment of vertical Y -axis hand
joint offset (green) adjustments to avoid elbow popping for the rig. Body lean was altered by increasing the Z-axis translation offset (blue) from both shoulder joint. Adjusting the body lean and the hand offsets were independent of each meaning, meaning that leaning the body backwards would not drag the hands with the body too.

Figure 3.3: Joint local axes that are affected by offsets

Figure 3.4 displays the specific numeric offsets used in the plugin to define the gesture change limits. The right hand was manually shifted slightly back than the left hand to reduce overlapping effects.

Figure 3.4: Offset settings for Malcolm (left) and Luna (right)

### 3.1.3 Stimuli Clips

With 4 factors, each one with 2 levels, a full factorial design would have involved 16 different possible combinations, and hence 16 different clips. Since such a high number of clips might have been difficult to rank, a partial factorial design was implemented. Using the JMP Pro 14 statistical software, the minimum number of clip variations needed to identify main effects (OG, FG, BL, and G) and two-way effects (OGxFG, OGxBL, FGxBL) in the study was determined to be 8 Table 3.2 lists the specific combinations used, and Figure 3.5 shows frames extracted from each of the 8 clips. The naming convention used to label the clips was the following: [G]_OG[x]-FG[x]-BL[x], where [G] was replaced by the gender initial of $M$ or $F$, and [ $x]$ was replaced by 1 or 2 to represent level.

Table 3.2: All clip combinations generated by JMP Pro 14

| $\#$ | Label | OG | FG | BL | G |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | M_OG2-FG1-BL2 | 2 | 1 | 2 | M |
| 2 | M_OG1-FG1-BL1 | 1 | 1 | 1 | M |
| 3 | M_OG1-FG2-BL2 | 1 | 2 | 2 | M |
| 4 | M_OG2-FG2-BL2 | 2 | 2 | 1 | M |
| 5 | F_OG1-FG1-BL2 | 1 | 1 | 2 | F |
| 6 | F_OG2-FG2-BL2 | 2 | 2 | 2 | F |
| 7 | F_OG1-FG2-BL1 | 1 | 2 | 1 | F |
| 8 | F_OG2-FG1-BL1 | 2 | 1 | 1 | F |

Figure 3.5: All clip combinations used in study

### 3.1.4 Survey Design and Delivery

The evaluation instrument was an online survey created in Qualtrics software. At the beginning of the survey, participants were asked to fill in information about their age, gender, and highest level of completed education. Next, participants were taken to the
valence question page. On this page, all eight clips were simultaneously loaded in a randomized order. Participants needed to drag and drop the clips, where the clip with the highest perceived valence would be dragged to the top. Once the participants completed the valence ranking page, they then proceeded to the arousal ranking page which featured re-randomized clips. They followed the same procedure to rank the clips from highest to lowest perceive arousal. The full survey is included in Appendix G.

Considering the possibility that the participants could rush through the surveys, a hidden timer was inserted on the valence and arousal ranking pages. The timer would record how long the participants spent on the survey page. The cut off point for eliminating rushed answers was preset to 22 seconds for each survey page, which was the length of watching two video clips.

The survey was administered through Amazon's Mechanical Turk and anybody 18 years or older was eligible to participate. Due to the distribution platform, both the maximum time limit and maximum number of study participants had to be preset. Based on the time results from a small-scale pilot test, the survey took roughly between 5-10 minutes to complete leading to the survey's maximum allotted time to be 20 minutes. In order to verify the survey results, the last page on the Qualtrics survey page generated a random five-digit number. This number had to be copied to the Mechanical Turk link page field, which was then manually compared and verified. Each participant was paid $\$ 1.50$ after their survey results were verified.

### 3.1.5 Data Analysis Methods

After data collection, IBM SPSS was used to conduct all data analysis tests. A 4way ANOVA was used to test main effects (OG, FG, BL, and G), as well as 2-way interactions (OGxFG, OGxBL, FGxBL). A significance level of $\alpha=0.05$ was used. In addition, a linear regression model was generated to examine how each factor may influence the mean rankings. A Chi-squared test was also performed to test the independence of the valence and arousal rankings.

Using the demographic collected from the participants, the full dataset was split into smaller subsets based on demographic categories. A 4-way ANOVA, a linear
regression model, and a Chi-squared test would then be applied to all subgroups. This was done to see if there were certain subgroups where some factors may be more significant than others.

### 3.1.6 Hypothesis

We formulated the hypothesis based on our findings from the literature review. In summary, an engaged agent would portray an emotion with high valence and arousal, meaning that the arms and hands are extended out and towards the viewer while the body is leaning forwards. In contrast, a disengaged agent would portray an emotion with low valence and arousal, meaning that the arms and hands are close to the body while the body is leaning backwards. Figure 3.6 provides a visualization based on above.

Figure 3.6: The relationship between body gestures with valence and arousal (NSFCyberlearning award \# 1821894, 2018)

Each main effect parameter and two-way effect parameter had a null and an alternate hypothesis for both valence and arousal rankings.

For valence, the hypotheses of the study were the follow:

- H1val_null: Modifying OG movement range does not affect a clip's mean valence ranking
- H1val_alt: Modifying OG movement range does affect a clip's mean valence ranking
- H2val_null: Modifying FG movement range does not affect a clip's mean valence ranking
- H2val_alt: Modifying FG movement range does affect a clip's mean valence ranking
- H3val_null: Modifying BL movement range does not affect a clip's mean valence ranking
- H3val_alt: Modifying BL movement range does affect a clip's mean valence ranking
- H4val_null: Modifying G movement range does not affect a clip's mean valence ranking
- H4val_alt: Modifying G movement range does not affect a clip's mean valence ranking
- H5val_null: Modifying OGxFG movement range does not affect a clip's mean valence ranking
- H5val_alt: Modifying OGxFG movement range does affect a clip's mean valence ranking
- H6val_null: Modifying OGxBL movement range does not affect a clip's mean valence ranking
- H6val_alt: Modifying OGxBL movement range does affect a clip's mean valence ranking
- H7val_null: Modifying FGxBL movement range does not affect a clip's mean valence ranking
- H7val_alt: Modifying FGxBL movement range does affect a clip's mean valence ranking

For Arousal, the hypotheses of the study were the following:

- H1aro_null: Modifying OG movement range does not affect a clip's mean arousal ranking
- H1aro_alt: Modifying OG movement range does affect a clip's mean arousal ranking
- H2aro_null: Modifying FG movement range does not affect a clip's mean arousal ranking
- H2aro_alt: Modifying FG movement range does affect a clip's mean arousal ranking
- H3aro_null: Modifying BL movement range does not affect a clip's mean arousal ranking
- H3aro_alt: Modifying BL movement range does affect a clip's mean arousal ranking
- H4aro_null: Modifying G movement range does not affect a clip's mean arousal ranking
- H4aro_alt: Modifying G movement range does not affect a clip's mean arousal ranking
- H5aro_null: Modifying OGxFG movement range does not affect a clip's mean arousal ranking
- H5aro_alt: Modifying OGxFG movement range does affect a clip's mean arousal ranking
- H6aro_null: Modifying OGxBL movement range does not affect a clip's mean arousal ranking
- H6aro_alt: Modifying OGxBL movement range does affect a clip's mean arousal ranking
- H7aro_null: Modifying FGxBL movement range does not affect a clip's mean arousal ranking
- H7aro_alt: Modifying FGxBL movement range does affect a clip's mean arousal ranking

We also tested the independence between arousal and valence rankings. The hypotheses were the following:

- HChi_null: The clip's valence and arousal ranking are both independent
- HChi_alt: The clip's valence and arousal ranking are both not independent

## CHAPTER 4. DATA COLLECTION AND ANALYSIS

### 4.1 Data Collection

A total of 120 verified responses were collected from the participants. All responses that showed a completion time under 22 seconds (the time length of watching 2 full clips) for either ranking page were removed from the study. This led to a total number of 103 filtered responses that were considered in the analysis. Appendix B includes the ranking means and standard deviations. The lower the ranking mean for a clip, the higher that clip is rated for valence or arousal.

For valence, clip F_OG2-FG2-BL2 was ranked the highest ( $\mathrm{M}=3.77$, $\mathrm{SD}=2.23$ ) while clip M_OG1-FG1-BL1 was ranked the lowest ( $M=5.05$, $\mathrm{SD}=2.16$ ). As for arousal, clip M_OG1-FG2-BL2 had the highest rank ( $\mathrm{M}=3.97$, $\mathrm{SD}=2.29$ ), and clip F_OG1-FG2-BL1 had the lowest arousal rank ( $\mathrm{M}=4.69$, $\mathrm{SD}=2.23$ ). Figure 4.1 displays the boxplot for the full dataset valence ranking, and Figure 4.2 displays the boxplot for the full dataset arousal ranking.

Figure 4.1: Boxplot for main study valence ranking

Figure 4.2: Boxplot for main study arousal ranking

### 4.2 Data Analysis

A 4-way ANOVA was performed to test the effect of each factor variable (main effects) and then the effect of their combination (interaction effects). A Chi-squared test was performed to test valence and arousal ranking independence. Table 4.1 and 4.2 report the results from the ANOVA analysis, Table 4.3 and 4.4 report the results from linear regression analysis, and Table 4.5 report the results from the Chi-squared test.

A linear regression model was implemented to examine how much each factor affects the mean valence or arousal rankings. When performing linear regression for the body gesture main and two-way effects, level 1 was remapped to -1 and level 2 was remapped to 1, i.e., Modifying OG from level 1 to level 2 means Modifying OG from -1 to 1 in the linear regression model. As for mapping G, male has been remapped to -1 and female has been remapped to 1 . After the linear regression model was produced, the resulting $B$ value would be multiplied by $2(2 B)$ to obtain the proper value that indicates rank change.

### 4.3 Demographics

All the data analysis tests performed for the full dataset were also applied to different subgroups of varying demographics from the sample population. The same analysis procedure was performed on a smaller subset of the collected data based on the participant's age, gender, and highest level of education. Any participants that has marked "Prefer not to answer" for any specific categories would be excluded from the respective category in the analysis.

### 4.3.1 Age

The split was decided between the "18-30 year old" group and all other groups above the age of 31 . This led to having the "18-30 Y/O" group having 45 subjects and the " $31+\mathrm{Y} / \mathrm{O} "$ group having 58 subjects.

### 4.3.2 Highest Level of Education

Most of the responses reported that they at least have a bachelor's degree. The category split was decided between participants that had a degree (Bachelor's or higher), and participants that did not have a degree.

### 4.3.3 Gender

The group split would logically be between male and female study participants. From the sample population, 66 reported as male and 37 reported as female.

### 4.3.4 Clip Rankings

For mean valence rankings, most of the subgroups agreed between two clips that were perceived with the highest valence. The female subset, and the $30+\mathrm{Y} / \mathrm{O}$ subset agreed with the main dataset that F_OG2-FG2-BL2 had the highest valence ranking ( $\mathrm{M}=$ 3.62 and $3.44, \mathrm{SD}=1.96$ and 2.39 ). The male subset, $18-30 \mathrm{Y} / \mathrm{O}$ subset, and degree subset all agreed on F_OG2-FG1-BL1 having the highest valence ( $\mathrm{M}=3.77,3.56$, and $3.75, \mathrm{SD}=1.81,1.82,1.87$ ). The no degree subset was the primary exception, stating that F_OG1-FG2-BL1 had the highest valence rank ( $\mathrm{M}=3.44$, $\mathrm{SD}=2.05$ ). All subgroups universally ranked male clips with lower valence. The female and the degree subset
agreed with the main dataset that M_OG1-FG1-BL1 had the lowest valence rank ( $\mathrm{M}=$ 5.22 and $5.14, \mathrm{SD}=2.08$ and 2.1) The male subset, $30+\mathrm{Y} / \mathrm{O}$ subset, and no degree subset all agreed that M_OG2-FG2-BL1 had the lowest valence rank ( $\mathrm{M}=5.35,5.54$ and 5.47, $\mathrm{SD}=2.29,2.28,2.18$ ). The 18-30 Y/O subset claimed that M_OG1-FG2-BL2 had the lowest valence rank $(M=5.38, S D=2.33)$

As for mean arousal rankings, the male subset, female subset, 18-30 Y/O subset, no degree subset, and degree subset all agreed with the full dataset that M_OG1-FG2-BL2 had the highest valence ranking ( $\mathrm{M}=3.97,4.03,3.86,3.62,4.06$, and $3.93, \mathrm{SD}=2.25$, 2.35, 2.28, 2.36, and 2.25). The 30+Y/O subset stated that M_OG1-FG1-BL1 had the highest arousal rank ( $\mathrm{M}=4.16, \mathrm{SD}=2.25$ ). As for the lowest ranked arousal clip, the male subset, 30+ Y/O subset, and the degree subset agreed with the full dataset that F_OG2-FG2-BL2 was the lowest ( $\mathrm{M}=4.95,5.05$, and 5.06, $\mathrm{SD}=2.28,2.31,2.36$ ). The 18-30 Y/O subset and the no degree subset stated that F_OG1-FG2-BL1 had the lowest arousal rank ( $\mathrm{M}=5.04$ and $5.5, \mathrm{SD}=2.19,2.26$ ). The female subset stated that F_OG2-FG1-BL1 had the lowest arousal rank $(M=4.92, S D=2.26)$.

### 4.4 Discussion

Factor variable G showed statistical significance ( $\mathrm{P}=$ nearly 0.000 ) for the valence rankings, allowing us to reject H 4 val_null. G was also the only factor variable that was significant for arousal rankings $(\mathrm{P}=0.015)$, allowing us to reject H 4 aro_null. OG was close to statistically significance, $(\mathrm{P}=0.083)$ for valence.

According to the linear regression model for valence and arousal, Modifying G from male to female changed the mean valence ranking by nearly a full rank ( $2 \mathrm{~B}=-$ 1.048), and about four-tenths of an arousal rank ( $2 \mathrm{~B}=-0.388$ ). Overall, the data supported that Gender was a significant main effect for both valence and arousal rankings; the clips featuring the female agent were ranked significantly higher for valence and arousal than the clips featuring the male agent.

In regard to the demographic subsets, for the valence rankings, Gender was a significant main effect for the 18-30 Y/O subset, the male subset, the female subset, the no-degree subset and the degree subset $(\mathrm{P}=0.000,0.000,0.001,0.000$, and 0.00$)$ by at
least half a rank ( $2 \mathrm{~B} \approx-0.500$ ). This allows us to reject H 4 val _null, giving evidence that clips with the female agent has a higher perceived valence for the listed categories than the clips with the male agent. Interestingly, the 18-30 Y/O subset also suggests that OG and BL are significant $(\mathrm{P}=0.034$ and 0.042$)$ for influencing the valance rankings, with OG raising the valence ranking $(2 \mathrm{~B}=-0.5)$ and BL decreasing valence ranking ( $2 \mathrm{~B}=$ 0.478 ) when the factor level changes from level 1 to level 2 for both parameters. We can reject H1val_null and H3val_null and accept H1val_alt and H3val_alt. This suggests that for the 18-30 Y/O group increasing OG from level 1 to level 2 results in higher perceived valence but increasing BL likewise would result in decrease perceived valence.

As for arousal rankings, only the 18-30 Y/O subset and the female subset suggests that G influences the arousal rankings ( $\mathrm{P}=0.019$ and 0.023 ), allowing us to reject H4aro_null for the two listed categories. According to the linear regression model, Modifying G from male to female for the listed groups would result in higher perceived arousal (2B values of -0.566 and -0.608 ).

The Chi-squared test that was performed on the main dataset, yielded a P-value of 0.037 , hence we could reject HChi_null: the valence and arousal rankings during the survey were not-independent of each other for the full dataset. Another instance where the Chi-squared test has shown significance was for the male subset, in which the P -value was 0.011 . This also meant that HChi_null could be rejected for the male subset. It should be noted that for all the datasets, the reported R-squared values were very low. From the main dataset, the valence $\mathrm{R}^{2}$ value was 0.056 and the arousal $\mathrm{R}^{2}$ value was 0.013 . The $R^{2}$ values from the subsets all did not exceed 0.150 . The low $R^{2}$ suggests that even if the data points suggest a relationship between factors and perceived valence/arousal, the exact relationship may differ from the suggest linear model.

## CHAPTER 5. STUDY 2

Two factors in the first study might have affected the participant's rankings. First, the order of the valence and arousal ranking pages was not randomized, meaning that study participants would always rank clips for valence first and arousal second. Unfortunately, study participants overall spent less time on the arousal page, with an average time spent on the arousal ranking page being 107.32s compared to valence ranking page average completion time of 232.87s. In the 2 nd study the question page ordering was fully randomized.

Second, we suspected that the ranking procedure might have been difficult to perform for some of the participants. Not only might the gesture differences be difficult to spot across all eight main-study clips, but the participants might only have been able to view 2-3 clips on screen at once due to the survey design, further making it difficult to compare eight clips at once. The second study changed the question format so that participants were only rating one clip at a time.

Lastly, we suspected that putting the male and the female agents clips together could help exaggerate expressiveness from one of the agents. Potential reasons why G was the sole significant influential factor from the main study could be because of the different voice performances between male and female actors, the agent's clothing color, or the agent's body proportion (i.e. the male agent has larger hands compared with the female agent). Study 2 used a between subject design and assigned one group of subjects to the female agent clip and one group of subjects to the male agent clip so that gender comparison bias within the same survey would not be introduced.

### 5.1 Changes in Methodology

Study 2 included two separate surveys which were administered using Amazon's Mechanical Turk; one restriction was added, e.g., study participants had to have a Master Worker rating --participants that have statistically demonstrated a higher degree of
success. Each study participant was paid $\$ 1.00$ after their survey answers were verified. A time filter of 11 seconds (length of one video clip) was used to remove rushed answers.

Both surveys featured the same body gesture changes, but the agent's gender differed between the surveys. Another partial factorial design was generated using JMP Pro 14. Table 5.1 displays the updated clip set which contains 8 different combinations. Both a male and a female variant of clips were generated, resulting in a total of 16 different video clips. Figure 5.1 includes 16 frames, each one extracted from each clip.

Table 5.1: New clip combinations for follow-up study

| $\#$ | Label | OG | FG | BL |
| :--- | :--- | :--- | :--- | :--- |
| 1 | M_OG2-FG1-BL2, <br> F_OG2-FG1-BL2 | 2 | 1 | 2 |
| 2 | M_OG1-FG1-BL2, <br> F_OG1-FG1-BL2 | 1 | 1 | 2 |
| 3 | M_OG2-FG2-BL2, <br> F_OG2-FG2-BL2 | M_OG1-FG2-BL2, <br> F_OG1-FG2-BL2 | 1 | 2 |
| 5 | M_OG1-FG1-BL1, <br> F_OG1-FG1-BL1 | 1 | 2 | 2 |
| 6 | M_OG2-FG2-BL1, <br> F_OG2-FG2-BL1 | 2 | 1 | 1 |
| 7 | M_OG1-FG2-BL1, <br> F_OG1-FG2-BL1 | 2 | 2 | 1 |
| 8 | M_OG2-FG1-BL1, <br> F_OG2-FG1-BL1 | 1 | 1 |  |

Figure 5.1: All clip combinations used in follow-up study

After viewing each clip, participants were asked to rate the clip's valence and arousal values using a 7-point Likert scale from 10 to 70. In this study for valence, 10 represented negative valence and 70 represented positive valence. As for arousal, 10 represented low arousal and 70 represented high arousal. Participants could re-watch and re-rate any video clip as many times as needed, only the final answers were reported.

### 5.2 Hypothesis

The null and alternate hypothesis used in the follow-up study would be like the main study, with the main difference being that the dependent variable was the mean valence and arousal rating instead of the mean valence and arousal ranking.

- H1val_null: Modifying OG movement range does not affect a clip's mean valence rating
- H1val_alt: Modifying OG movement range does affect a clip's mean valence rating
- H2val_null: Modifying FG movement range does not affect a clip's mean valence rating
- H2val_alt: Modifying FG movement range does affect a clip's mean valence rating
- H3val_null: Modifying BL movement range does not affect a clip's mean valence rating
- H3val_alt: Modifying BL movement range does affect a clip's mean valence rating
- H4val_null: Modifying G movement range does not affect a clip's mean valence rating
- H4val_alt: Modifying G movement range does not affect a clip's mean valence rating
- H5val_null: Modifying OGxFG movement range does not affect a clip's mean valence rating
- H5val_alt: Modifying OGxFG movement range does affect a clip's mean valence rating
- H6val_null: Modifying OGxBL movement range does not affect a clip's mean valence rating
- H6val_alt: Modifying OGxBL movement range does affect a clip's mean valence rating
- H7val_null: Modifying FGxBL movement range does not affect a clip's mean valence rating
- H7val_alt: Modifying FGxBL movement range does affect a clip's mean valence rating

A similar set of null and alternate hypothesis could be applied for the clip's arousal ranking:

- H1aro_null: Modifying OG movement range does not affect a clip's mean arousal rating
- H1aro_alt: Modifying OG movement range does affect a clip's mean arousal rating
- H2aro_null: Modifying FG movement range does not affect a clip's mean arousal rating
- H2aro_alt: Modifying FG movement range does affect a clip's mean arousal rating
- H3aro_null: Modifying BL movement range does not affect a clip's mean arousal rating
- H3aro_alt: Modifying BL movement range does affect a clip's mean arousal rating
- H4aro_null: Modifying G movement range does not affect a clip's mean arousal rating
- H4aro_alt: Modifying G movement range does not affect a clip's mean arousal rating
- H5aro_null: Modifying OGxFG movement range does not affect a clip's mean arousal rating
- H5aro_alt: Modifying OGxFG movement range does affect a clip's mean arousal rating
- H6aro_null: Modifying OGxBL movement range does not affect a clip's mean arousal rating
- H6aro_alt: Modifying OGxBL movement range does affect a clip's mean arousal rating
- H7aro_null: Modifying FGxBL movement range does not affect a clip's mean arousal rating
- H7aro_alt: Modifying FGxBL movement range does affect a clip's mean arousal rating

### 5.3 Data Analysis

The data analysis methods were the same as in study 1. A 4-way ANOVA analysis was used to test main and two-way effects for valence and arousal ratings. A linear regression model was fit for each dependent variable to determine how the factors could affect the ratings. Unlike study 1, the Chi-squared test could not be performed as there were too many possible rating values. Table 5.2 and 5.3 report the results from the ANOVA analysis, and Table 5.4 and 5.5 report the results from linear regression analysis.

A linear regression model was also implemented to estimate how much each factor affects the mean valence or arousal ratings. Just like analysis performed in study 1 for the body gesture main and two-way effects, level 1 was remapped to -1 and level 2 was remapped to 1 . As for mapping G, male was remapped to -1 and female was remapped to 1 . The resulting B value was multiplied by $2(2 B)$ to obtain the proper value that indicated rank change amount.

### 5.4 Results

A total of 300 verified responses was collected, with 150 results collected independently from both the male and female agent survey. After applying the time filter, this reduced the male survey count to 134 filtered responses and the female survey count to 139 filtered responses. The survey's filtered raw data can be found in Appendix D, basic statistics can be found in Appendix E, and all the statistical analyses performed on the full and partial datasets can be found in Appendix F. Figure 5.2 and 5.3 show the boxplot for the valence and arousal ranking, respectively.

From the main dataset, the clip with the highest valence rating was F_OG2-FG2BL1 ( $M=50.6, S D=9.49$ ), and the clip with highest arousal rating was M_OG2-FG2BL1 $(M=52.27, S D=10.31)$. The clip with the lowest valence rating was M_OG1-FG1BL1 $(\mathrm{M}=45.24, \mathrm{SD}=10.23)$ and the clip with the lowest arousal rating was F_OG1-FG1-BL1 ( $\mathrm{M}=47.67, \mathrm{SD}=11.34$ )

### 5.5 Demographics

The same divisions from the main study were used again for the follow-up. The following tables display the demographic distributions when combining the sample population from both the male and female agent survey. The fields M count and F count represent the separate counts from their respective surveys.

### 5.5.1 Age

The 18-30 y/o subset has 53 participants, and the 30+y/o subset has 217 participants. Compared to the main study sample population, there is a smaller proportion number of 18-30 year old participants.

### 5.5.2 Highest level of education

The no degree subset has 83 participants, and the degree subset has 186 participants. Compared to the main study sample population, there is a smaller proportionate number of participants that do not have a college degree.

### 5.5.3 Gender

The male subset has 182 participants, and the female subset has 89 participants. Survey participants were still mostly male, making up nearly two-thirds of the follow-up sample population.

### 5.5.4 Clip Rankings

For gender, the male subgroup agreed with the main dataset in both the highest rated valence clip F_OG2-FG2-BL1 $(\mathrm{M}=49.92, \mathrm{SD}=9.63)$ and the highest rated arousal clip M_OG2-FG2-BL1 $(\mathrm{M}=52.58, \mathrm{SD}=9.76)$. The female subgroup rated F_OG2-FG1BL1 having the highest valence rating ( $\mathrm{M}=52.24, \mathrm{SD}=9.29$ ), and F_OG2-FG2-BL2 having the highest arousal rating $(M=53.56, S D=10.4)$. The lowest ranked clips for males were M_OG1-FG1-BL2 (valence $\mathrm{M}=45.87, \mathrm{SD}=9.65$ ) and F_OG1-FG1-BL1 (arousal $\mathrm{M}=46.18, \mathrm{SD}=11.76$ ), and for females were $\mathrm{M} \_$OG1-FG1-BL2 (valence $\mathrm{M}=$ 43.54, $\mathrm{SD}=10.22$ ) and M_OG1-FG2-BL2 (arousal $\mathrm{M}=46.76$, $\mathrm{SD}=13.33$ ).

For age, both subsets rated F_OG2-FG2-BL1 (valence $\mathrm{M}=52.48$ and 50.14, valence $\mathrm{SD}=11.14$ and 9.1) and M_OG2-FG2-BL1 (arousal $\mathrm{M}=54.97$ and 51.7, arousal $\mathrm{SD}=8.75$ and 10.42) the highest. The lowest ranked clips for 18-30 Y/O subset were M_OG1-FG1-BL2 (valence $\mathrm{M}=43.73, \mathrm{SD}=10.78$ ) and F -OG1-FG2-BL2 (valence $\mathrm{M}=$ 44.87 , $\mathrm{SD}=15.1$ ), and for $30+\mathrm{Y} / \mathrm{O}$ subset was M_OG1-FG1-BL1 (valence $\mathrm{M}=44.45$, valence $\mathrm{SD}=9.52$, arousal $\mathrm{M}=47.15$, arousal $\mathrm{SD}=10.19$ )

For highest level of education, both subsets rated F_OG2-FG2-BL1 (valence $\mathrm{M}=$ 48.75 and 51.25, valence $\mathrm{SD}=9.32$ and 9.49) and M_OG2-FG2-BL1 (arousal $\mathrm{M}=51.84$ and 52.7, arousal $\mathrm{SD}=9.78$ and 10.39) the highest. The lowest ranked clips for the nodegree subset were M_OG1-FG1-BL2 (valence $\mathrm{M}=42.91$, $\mathrm{SD}=8.16$ ) and F_OG1-FG1BL1 (arousal $\mathrm{M}=46.15, \mathrm{SD}=8.82$ ), and for the degree subset were M_OG1-FG1-BL1 (valence $\mathrm{M}=45.73, \mathrm{SD}=10.21$ ) and M _OG1-FG2-BL2 (arousal $\mathrm{M}=47.91, \mathrm{SD}=$ 13.21).

### 5.6 Discussion

Compared with the main study, more factors shown significance after performing a 4-way ANOVA test. For valence, all main factors were significant for affecting the mean valence rating ( $\mathrm{OG} \mathrm{P}=0.003$, $\mathrm{FG} \mathrm{P}=0.012, \mathrm{BL} \mathrm{P}=0.022$, $\mathrm{GP}=$ nearly 0.000 ). This meant that H1val_null, H2val_null, H3val_null, and H4val_null could all be rejected, leading to H1val_alt, H2val_alt, H3val_alt, and H4val_alt all being accepted. As for valence, OG and FG were tested to be significant ( $\mathrm{OG} \mathrm{P}=0.000$, $\mathrm{FG} \mathrm{P}=0.017$. This allowed H1aro_null and H2aro_null to be rejected, allowing H1aro_alt and H2aro_alt to be accepted. Overall, the collected data does support that OG, FG, BL and G does influence the mean valence ratings, and that OG and FG does influence the mean arousal ratings.

After applying the linear regression model to the full follow-up dataset, the model still shows that G is the most influential factor for valence $(2 \mathrm{~B}=2.548)$ when G is changed from male to female. OG, FG, and BL influence the valence mean by a smaller amount when the parameters are changed from level 1 to level 2 with OG 2B equaling 1.272 and FG 2 B equaling 1.082 , and especially BL 2 B equaling -0.982 , meaning that BL
has a negative relationship. As for arousal, OG is the most influential factor when increased from level 1 to level $2(2 \mathrm{~B}=2.038)$. FG also influences the mean with a 2 B of 1.136 from level 1 to 2 .

When looking at different demographic subsets, some parameters are still significant in agreement with the full dataset data analysis. All subgroups except the 1830 Y/O group demonstrated that OG is a significant factor for influencing the mean valence rating ( $30+\mathrm{Y} / \mathrm{O} \mathrm{OG} \mathrm{P}=0.014$, male $\mathrm{OG} \mathrm{P}=0.037$, female $\mathrm{OG} \mathrm{P}=0.013$, no degree $\mathrm{OG} \mathrm{P}=0.010$, degree $\mathrm{OG} \mathrm{P}=0.039$ ) and for influencing the mean arousal ( $30+$ Y/O OG $\mathrm{P}=$ nearly 0.000 , male $\mathrm{OG} \mathrm{P}=0.001$, female $\mathrm{OG} \mathrm{P}=0.004$, no degree $\mathrm{OG} \mathrm{P}=$ 0.006 , degree $\mathrm{OG} \mathrm{P}=0.001$ ). FG was a significant factor for male subset and the degree subset for valence (male FG $\mathrm{P}=0.014$, degree $\mathrm{FG} \mathrm{P}=0.041$ ) and was a significant factor for $30+\mathrm{Y} / \mathrm{O}$ subset and No Degree subset for arousal $(30+\mathrm{Y} / \mathrm{O} \mathrm{P}=0.019$, no degree $\mathrm{P}=$ 0.040). BL was only significant for the 18-30 Y/O subset and the no degree subset for valence (18-30 Y/O P $=0.001$, no degree $\mathrm{P}=0.041$ ), and $18-30 \mathrm{Y} / \mathrm{O}$ subset only for arousal ( $18-30 \mathrm{Y} / \mathrm{O} \mathrm{P}=0.008$ ). G was a significant factor for the $30+\mathrm{Y} / \mathrm{O}$ subset, female subset, no degree subset, and degree subset for valence $(30+\mathrm{Y} / \mathrm{O} \mathrm{P}=0.000$, female $\mathrm{P}=$ 0.000 , no degree $\mathrm{P}=0.045$, degree $\mathrm{P}=0.000$ ), and just the female subset for arousal (female $\mathrm{P}=0.035$ ).

The linear regression models performed on the subsets primarily matched up with the main dataset for many of the factors. Two notable exceptions were the BL parameters for valence ratings for the 18-30 Y/O subset and the G parameter for valence rating for the Female subset. According to the regression model, the Modifying BL from level 1 to level two would result in a 2 B equaling - 3.34 in comparison to the main study BL's 2B which was just -0.982 . As for the female subset, Modifying the G from male to female results in an 2B equaling 5.084 compared to the main study G's 2B of 2.548 .

Overall, the R-squared values have been low. The full dataset's $\mathrm{R}^{2}$ was 0.025 for valence and 0.013 for arousal. The largest $\mathrm{R}^{2}$ value when looking at the data subset was 0.073 , which was still very low. Just like Study 1 , the low $\mathrm{R}^{2}$ suggests that even if the data points suggest a relationship between factors and perceived valence/arousal, the exact relationship may differ from the suggest linear model.

## CHAPTER 6. CONCLUSION

The findings from the 2 studies were consistent with results of prior experiments reported in the literature review. They provided evidence that a positive-valence, high arousal pedagogical agent would need to open out the arms and hands more outwards, as OG was tested to be significant in affecting both perceived valence and arousal. The linear regression models stated that there was a positive relationship between the arms opening out and the viewer's perceived valence and arousal. Both OG2-FG2-BL1 clips in study 2 were perceived for having either the highest valence or arousal, where the arms were spread out in both those clips. The study's overall findings also provided evidence that a positive-valence, high arousal pedagogical agent would also need to physical reach out to the viewer more with arms and hands, as FG had a statistically significant main effect for both perceived valence and arousal. The linear regression models showed a positive relationship between stretching the arms forward and the perceived valence and arousal. The clips with the highest perceived valence or arousal were also the OG2-FG2BL1 clips as mentioned above.

The studies did not support prior research findings according to which engaging pedagogical agents would tend to lean forward more. While BL was tested to be significant in study 2 (both valence and arousal from the 18/30+Y/O subset and just valence from the full dataset), the linear regression model suggested that rotating the body forwards decreased the viewer's perceived valence and arousal of the agent. One possible explanation was that modifying BL via the custom script would modify the agent's body lean independently from the hand locations. For example, if BL was adjusted backwards, the hands and arms would not be dragged with the body too. As of a result, the backwards leaning motion of the agent could have been perceived more as a balancing action than an intentional action of the agent trying to reach out towards the viewer. This was further demonstrated in study 2 as the clips with the highest mean valence and arousal rating were both M_OG2-FG2-BL1 and F_OG2-FG2-BL1 clips; in these clips the agent's hands were spread wide open and towards the viewer while the agent's body was leaned backwards.

Gender surprisingly played the most important role for valence and arousal perception compared to body gesture adjustments. The main study only showed that G was the most significant factor for influencing valence rankings. G was also shown to be significant during the follow-up study for valence, with the linear regression model stating that G influenced the valence and arousal ratings more than any of the body gesture factors.

Some of the gender factors discussed in the literature review were backed up by this study's overall findings. Female agents appear to be more supportive; findings from both studies reveal that the female agent clips had higher perceived valence. This meant that these clips had more perceived positivity. According to the linear model regression from both studies, Modifying G from male to female resulted in a higher valence ranking or ratings. Only female clips had the highest perceived mean valence rankings or ratings in both studies. As for male agents being perceived to be more active (high arousal), both studies' findings were not able to statistically support this claim, despite that the clips with the highest perceived arousal were all male clips. Prior findings that suggest that participants find agents of opposite gender more engaging were not supported by our studies. Study 2 suggested that for female subset not only was G significant, but also female clips had higher perceived arousal.

While the study also attempted to determine if two-way factor interactions OGxFG, OGxBL, and FGxBL were significant, data analysis from both the first and second study were unable to confirm if these factors influenced valence or arousal perception. Only main effects OG, FG, BL and G had significance. The main study also claimed that valence and arousal ratings may not be independent of each other, but this would need further work to further detail their relationship.

### 6.1 Future Work

Despite the statistical claims in the study that G overall was a significant factor, we still had reservations if this truly was the case. Gender was not the only variable that differentiated the male agent from the female one, other possibly confounding variables such as agent's design, voice line delivery, and animation clip timings might have
affected subjects' ratings and rankings. Further studies would need to be performed to determine which of these factors might have affected the results the most. Further physical modifications on the agent could be tested for other possible factors based on the agent's appearance, such as the agent's race and gender.

While the study only focused on body gesture factors, animation factors could also affect the viewer's emotional perception of the agent. Two possible factors that could influence the agent's acting includes animation clip playback speeds and animation clip transition interpolation methods.

Overall, this study provided the basis for parameterizing pedagogical agent gesture adjustments in emotion studies. It provided a basis for further studies that investigate how the agent's attributes can be modified for the agent to better connect with the viewers.

## APPENDIX A. STUDY 1 DATA

The following tables list the raw data that was collected from the main online survey study. Columns C1 to C8 represents the given clip rank, from 1 being the highest to 8 being the lowest. The specific factor combinations for the 8 clips are listed in following table. The Time column on the furthest right represents the time the participant taken from page load to page submit.

| Clip | Valence Table Name | Arousal Table Name |
| :--- | :--- | :--- |
| M_OG2FG1BL2 | C1_V | C1_A |
| M_OG1FG1BL1 | C2_V | C2_A |
| M_OG1FG2BL2 | C3_V | C3_A |
| M_OG2FG2BL2 | C4_V | C4_A |
| F_OG1FG1BL2 | C5_V | C5_A |
| F_OG2FG2BL2 | C6_V | C6_A |
| F_OG1FG2BL1 | C7_V | C7_A |
| F_OG2FG1BL1 | C8_V | C8_A |

## DEMOGRAPHIC DATA

| Age Group | Count | Percentage |
| :--- | ---: | ---: |

## APPENDIX D. STUDY 2 DATA

The following tables list the raw data that was collected from the main online survey study. Columns C1 to C8 represents the given clip rank, from 1 being the highest to 8 being the lowest. The specific factor combinations for the 8 clips are listed in following table. There is both a male and a female variant for each combination.

| Clip | Valence Table Name | Arousal Table Name |
| :--- | :--- | :--- |
| M_OG2-FG1-BL2, <br> F_OG2-FG1-BL2 | C1_V | C1_A |

## APPENDIX G. STUDY 1 SURVEY FORMAT

## PURDUE <br> U N I V

Gestures \& Perceived Expression Comparison Survey
This survey is best done on a computer.
You will be asked to rank a total of 8 clips for two different factors:

- Valence - Showcasing the amount of positivity of an expression
- Arousal - Showcasing the amount of energy present in an expression

The following table may help for classifying the items:

|  | Low | High |
| :--- | :--- | :--- |
| Valence | Sad / Angry | Happy / Excited |
| Arousal | Tired / Dis-interested | Energetic / Interested |

A clip with greater Valence will look more happier than the other clip. A clip with greater Arousal would look more energetic than the other clip.

Please rank the clips based on body language differences. You can replay the clips as many times as needed, and you do not have a time limit to complete the survey.

Click the next button to continue with the survey.

## $\square D T D T E T$ <br> $\begin{array}{llllllllll}\mathrm{U} & \mathrm{N} & \mathrm{I} & \mathrm{V} & \mathrm{E} & \mathrm{R} & \mathrm{S} & \mathrm{I} & \mathrm{T} & \mathrm{Y}\end{array}$

## Demographic Information

Please fill out the demographic information below. If you do not wish to answer the question, please select "Prefer not to answer"

What is your age?
18-30 years old31-43 years old$43-55$ years old55-67 years old68 years old or olderPrefer not to answer

What is your gender?MaleFemalePrefer not to answer

What is your highest completed level of Education?Did not finish high school or earlierHigh School graduateSome college, no degreeBachelor's DegreeMasters Degree or equivalentPhD or equivalentPrefer not to answer
$\rightarrow$

The survey will begin on the next page. Click the next button to proceed.

## PURDUE <br> U N I V E R S I T Y

Ranking Valence

Refer to the following table when ranking the clips on this page:

| High Valence | Low Valence |
| :--- | :--- |
| Looks happy | Looks sad / angry |

Rank the clips from GREATEST to LEAST amount of VALENCE (positivity). The highest ranked clip should be at the top. Drag / drop the answers until you get the desired ranking.

## PURDUE <br> U N I V

Ranking Arousal

Refer to the following table when ranking the clips on this page:

| High Arousal | Low Arousal |
| :--- | :--- |
| Looks interested towards viewer | Looks disinterested / tired |

Rank the clips from the GREATEST to LEAST amount of AROUSAL (energy). The highest ranked clip should be at the top. Drag / drop the video clops answers until you get the desired ranking.

Here is your survey completion ID:

Copy this value to paste into MTurk.

Once you are done, please click the next button to submit your survey.

## APPENDIX H. STUDY 2 SURVEY FORMAT

## PURDUE <br> U N I V E R S I T Y 。

Gestures \& Perceived Emotion Comparison Survey (Male Clips)

PLEASE READ CAREFULLY. This survey is best done on a computer.

For purposes of our project, we define emotion as a psychological state consisting of the conscious experience or feeling of affect.

We adopt Russell's (2003) model of core affect, in which any particular emotion can be placed along two dimensions--(1) valence--ranging from positive (pleasure) to negative (displeasure), and (2) arousal--ranging from activation to deactivation. As shown in the Figure below, the vertical axis (arousal) ranges from deactivation to activation, and the horizontal axis (valence) ranges from displeasure to pleasure. Accordingly, emotions such as stressed or upset belong in the upper-left quadrant (negative valence, high arousal); happy and excited belong in the upper-right quadrant (positive valence, high arousal), content and relaxed belong in the lowerright quadrant (positive valence, low arousal), and sad and depressed belong in the lower-left quadrant (negative valence, low arousal).

Please watch the animated clips and pay attention to the emotion displayed by the character in each clip. For each clip, answer the following 2 rating questions:

- Valence: How pleasant/positive is the emotion displayed by the character? Rate from 10 to 70 ( $10=$ highly unpleasant/negative; $70=$ highly pleasant/positive)
- Arousal: How active/engaged is the character? Rate from 10 to $70(10=$ highly inactive/not engaged; $70=$ highly active/engaged)

You can replay the clips as many times as needed, and you can enlarge the clip to full screen. You can also return to previous clips that you have already watched. Only your final answer will be recorded.

After completing the survey, you will recieve a Random ID number. Please copy and paste this ID number into the ID field on the Mechanical Turk hit page.

Click the next button to continue with the survey.
