Approved by:
Dr. Duane Dunlap

You don't have to be a product of your environment.
Dare to learn and explore, but never forget where you came from.

## ACKNOWLEDGMENTS

First and foremost, I would like to express my appreciation to my fellow research committee members Dr. Richard Mark French, Dr. José Garcia Bravo, and Rajarshi Choudhuri. The following study would not have been accomplished without your support, guidance, and knowledge.

Dr. French, I specifically would like to address your unconditional willingness to help me out from day one of graduate school. I was a graduate student without funding due to unforeseen circumstances, and you presented me the opportunity to join the Technical Assistance Program (TAP) to resolve those conflicts. You have taught me innumerable lessons about engineering and life in general. Furthermore, you and Amy always provided the most warming hospitality imaginable. I can never repay you and Amy for all the baked goodies and feasts throughout my graduate program.

Dad, you have taught me countless lessons about mental fortitude, sacrifice, self-discipline, and work ethic. Mom, you have taught me countless lessons on how to be grateful and appreciate who and what I have. Josh, you have always inspired me to believe in myself, chase down goals, and trust my instincts. Morgan, you have helped me develop emotional intelligence and demonstrated how to be open-minded. Taylor, you have shown me how it is never too late to change the road you are on and make a change for the better. Sylvia, you motivate me to never give up regardless of the challenges ahead. Also, I would like to express my deep love and gratitude to other family members and close friends. Every one of you give me the courage to be what I am destined to be. Without out all of you, I am an unfinished puzzle.

Lastly, I would like to send out appreciation for a few other individuals involved and highlight specific moments throughout my research. Dan Pickett and Dad, I could never repay you for your expertise in CNC machining and willingness to help me during stressful times when I have limited resources to manufacture components. Devon Pessler, I am indebted to you for all the assistance and helping me stay sane during all-nighters in the lab. Doug and Matt Davis, thank you for providing me with a workspace at odd hours, seemingly endless amounts of tools, and assistance assembling the wooden structure.

## GLOSSARY

| Dynamic system | A system that consists of a mass-spring-damper and has a response <br> to a specific input or is in free response (Choudhuri \& French, <br> 2018). |
| :--- | :--- |
| Fractional calculus | A mathematical tool that utilizes a fractional order or imaginary <br> number order of a differentiation or integration operator in an <br> expression (Kulish \& Lage, 2002). |
| Homogenous field | A mathematical definition of a space that possess properties that <br> are the same throughout the space, such as, an ideal fluid or gas <br> (Choudhuri \& French, 2018). |
| Mathematical model | A set of equations and axioms that describe a physical behavior <br> under a certain set of constraints (Choudhuri \& French, 2018). |
| Mittag-Leffler Function | A generalized two parameter complex function that is used for <br>  <br> Popolizio, 2018). |
| Navier-Stokes | A general equation that mathematically describes the motion of an <br> object in a homogenous field (Choudhuri \& French, 2018). |
| Riemann-Liouville | A generalized form for evaluating an integral of fractional order <br> (Magin, 2006). |

## NOMENCLATURE

| ${ }_{a} D_{b}^{a}$ | Fractional order derivative of a function from limit a to $b$ of order $\alpha$ | $\tau \theta \theta$ | Angular shear stress of the fluid on the cylinder |
| :---: | :---: | :---: | :---: |
| $\Gamma(\mathrm{x})$ | Euler's Gamma function of x | $G_{3}$ | Three parameter notation for Green's function |
| $E_{\alpha, \beta}(x)$ | Two parameter Mittag-Leffler function of $x$ | $\mathrm{t}_{\mathrm{p}}$ | Planck's time $=5.39106 \times 10^{-44}$ seconds |
| m | Mass of an object | I | Second moment of area |
| c | Damping constant | G | Shear modulus (of steel) |
| k | Spring constant | h | Height (of the disk) |
| $\lambda$ | Eigen value | $r_{\text {outer }}$ | Outer radius (of the disk) |
| $\zeta$ | Damping ratio | $r_{\text {inner }}$ | Inner radius (of the disk) |
| $\omega$ | Frequency | $D_{\text {spring }}$ | Diameter of the torsional spring |
| $\omega_{n}$ | Natural frequency | $L_{\text {spring }}$ | Length of the torsional spring |
| $\omega d$ | Damped frequency | t | Time (seconds) |
| $\phi$ | Phase difference |  |  |
| Re | Reynolds number |  |  |
| $l_{*}$ | Viscous length scale of the disk (top cross section of the cylinder) |  |  |
| $\Omega_{\mathrm{z}}$ | Angular acceleration |  |  |
| $c_{f}$ | Skin friction coefficient |  |  |
| $v_{\tau}$ | Angular shear stress friction velocity |  |  |
| $v_{r}$ | Velocity in the radial direction |  |  |
| $v_{\theta}$ | Velocity in the angular direction |  |  |
| $v_{z}$ | Velocity in the vertical (zaxis) direction |  |  |
| $\rho$ | Density of the material |  |  |
| $\mu$ | Viscosity of the fluid |  |  |

#### Abstract

Fractional calculus is the integration and differentiation to an arbitrary or fractional order. The techniques of fractional calculus are not commonly taught in engineering curricula since physical laws are expressed in integer order notation. Dr. Richard Magin (2006) notes how engineers occasionally encounter dynamic systems in which the integer order methods do not properly model the physical characteristics and lead to numerous mathematical operations. In the following study, the application of fractional order calculus to approximate the angular position of the disk oscillating in a Newtonian fluid was experimentally validated. The proposed experimental study was conducted to model the nonlinear response of an oscillating system using fractional order calculus. The integer and fractional order mathematical models solved the differential equation of motion specific to the experiment. The experimental results were compared to the integer order and the fractional order analytical solutions. The fractional order mathematical model in this study approximated the nonlinear response of the designed system by using the Bagley and Torvik fractional derivative. The analytical results of the experiment indicate that either the integer or fractional order methods can be used to approximate the angular position of the disk oscillating in the homogeneous solution. The following research was in collaboration with Dr. Richard Mark French, Dr. Garcia Bravo, and Rajarshi Choudhuri, and the experimental design was derived from the previous experiments conducted in 2018.

## CHAPTER 1. INTRODUCTION

### 1.1 Overview

Newton and Leibniz founded integer order calculus in the seventeenth century by developing a general symbolic and systematic method of analytical operations. Fractional calculus - the integration and differentiation to an arbitrary or fractional order-was conceptualized nearly the same time as integer order calculus (Kulish \& Lage, 2002). Fractional calculus techniques are applied in the following experiment to model the nonlinear response of the proposed oscillatory dynamic system. The comparison of the fractional and integer order model data determines if the oscillatory decay of the spring-damped system demonstrates fractional dynamic behavior.

### 1.2 Significance

The techniques of fractional calculus are not commonly taught in engineering curricula since physical laws are expressed by integer order notation. Engineers, however, encounter situations in which the integer order methods do not properly model the physical characteristics of a dynamic system and lead to numerous mathematical operations (Magin, 2006). Magin (2006) provides an example-derived from the original work of Torvik and Bagley (1984)— where fractional calculus provided an alternative solution for the surface shear stress developed by the transverse motion of a rigid flat plate in a homogeneous fluid. Kulish and Lage (2002) demonstrated how fractional calculus methods yield the same result in one operation as integer order calculus does in three operations. Fractional and integer order methods were applied in the proposed experiment to model the angular position of the disk while oscillating in the homogeneous fluid. The results from the analyses were then compared to the experimental results. The oscillatory decay in the system exhibited fractional behavior since the experimental results match the results obtained from the fractional analysis.

### 1.3 Statement of Purpose

The problem addressed by the following experimental study is that integer order calculus does not accurately model all the necessary physical characteristics of dynamic systems and produces numerous mathematical operations (Magin, 2006). The purpose of the study was to experimentally validate the fractional order model of the proposed dynamic system by considering the closeness of fit between the fractional and integer order models compared to the experimental data.

### 1.4 Experimental Setup

The proposed system, derived from previous experiments conducted by Choudhuri and French (2018), was designed as an aluminum disk rotating about the vertical axis of a stainlesssteel shaft where both ends were supported by bearings. The upper-support beam fixed the top end of the torsional spring. The bottom of the torsional spring connected to the upper part of the shaft to enable the oscillating motion in the system. The aluminum disk and stainless-steel shaft were joined using a force fit. The bottom end of the shaft was supported by a ball bearing in which was attached to the bottom of the tank containing the homogeneous fluid. Figure 1.1 illustrates the ideal experimental configuration.

Figure 1.1 Ideal experimental setup (Choudhuri \& French, 2018).

### 1.5 Assumptions

The assumptions of the experiment are listed as follows:

- The boundary conditions at the tank walls do not affect the motion of the disk since the diameter of the tank is significantly larger (at least 3x) than the diameter of the disk.
- Fluid boundary layer effects on the shaft are negligible.
- The surface finish of the disk is uniform meaning that the coefficient of drag is uniform along the surface.
- The contact point between the bottom of the shaft and the bearing fixed to the bottom of the tank is frictionless.
- The homogeneous fluid used in the experiment is considered ideal.

### 1.6 Limitations

The limitations of the experiment are listed as follows:

- The static and dynamic relationship of the shaft and the disk must remain perpendicular.
- Inertial forces must be high enough, compared to the spring and damping forces, to prevent rapid oscillatory decay.
- The fatigue stresses acting on the torsional spring after each experiment run incurs losses thus the spring must be replaced after each run.

### 1.7 Delimitations

The delimitations of the experiment are listed as follows:

- Fluid boundary layer formation on the vertical shaft is not considered.
- Variation of the cross-sectional area of the aluminum disk is not considered as it has been machined with tight tolerances and is considered uniform.
- Variation of the surface finish on the top and bottom face of the aluminum disk is not considered as it has been machined with tight tolerances and is considered uniform.
- The alignment of the stainless-steel shaft and aluminum disk is considered perpendicular due to careful machining and tight tolerances.

### 1.8 Chapter Summary

Newton and Leibniz established the foundations of integer order and fractional order calculus in the seventeenth century. Fractional order calculus is a mathematical concept in which integration and differentiation is to an arbitrary, non-integer order (Kulish \& Lage, 2002). The fractional and integer order differential equations corresponding to the experiment were evaluated to model the dynamics of the oscillating system. The purpose of this study was to experimentally validate the application of fractional order calculus to approximate the angular position of the oscillating disk in a homogeneous fluid. The following chapter goes into further details regarding the history, fundamental theories, and applications of fractional order calculus.

## CHAPTER 2. REVIEW OF LITERATURE

### 2.1 Brief History of Fractional Order Calculus

The foundations of calculus emerged during the third century after Archimedes, the father of statics, computed areas, volumes, and lengths of arcs by methods of exhaustion. The method of exhaustion computed the desired area by inscribing polygons in a circle with an increasing number of edges in which the area of the polygons converges to the area of the containing shape (Rosenthal, 1951). Efforts from Stevin, Valerio, Kepler, Cavalieri, Fermat, Pascal, Descartes, and many others set the stage for the two founding fathers of calculus. Newton and Leibniz independently founded integer order calculus by developing a general symbolic and systematic method of analytical operations independent of geometry during the seventeenth century (Rosenthal, 1951). The integer order notation $\frac{d f(x)}{d x}$ or $D^{1} f(x), \frac{d^{2} f(x)}{d x^{2}}$ or $D^{2} f(x)$ is a familiar concept. However, the fractional order notation $\frac{d^{\frac{1}{2}} f(x)}{d x^{\frac{1}{2}}}$ or $D^{\frac{1}{2}} f(x)$ is not easily recognized, because textbooks often do not incorporate lessons on fractional order concepts (Kleinz \& Osler, 2000). Fractional calculus-the method of integration and differentiation to an arbitrary, non-integer order-was conceived nearly the same time as integer order calculus in 1695 (Kulish \& Lage, 2002). Fractional calculus operations are demonstrated on functions of engineering interest with emphasis on Laplace transform methods to solve initial value problems in the time domain and provide expressions describing sinusoidal steady-state behavior in the following text. In real analyses, fractional order calculus is the generalization of integer order calculus.

### 2.2 Fractional Order Calculus Explained

### 2.2.1 Fractional Derivative of Exponential Functions

Kleinz \& Osler (2000) provide an explanation of fractional order calculus by examining the exponential function below in equation 2.1.

$$
\begin{equation*}
f(x)=e^{p x} \tag{2.1}
\end{equation*}
$$

The corresponding integer-based derivative of the first, second, and third order are shown below in equation 2.2.

$$
\begin{gather*}
f^{1}(x)=D^{1} e^{p x}=p^{1} * e^{p x} \\
f^{2}(x)=D^{2} e^{p x}=p^{2} * e^{p x}  \tag{2.2}\\
f^{3}(x)=D^{3} e^{p x}=p^{3} * e^{p x}
\end{gather*}
$$

Assume that $n$ is an integer number and $\alpha$ is a rational number. The general form of the integer derivative of equation 2.2 is shown below in equation 2.3.

$$
\begin{equation*}
f^{n}(x)=D^{n} e^{p x}=p^{n} * e^{p x} \tag{2.3}
\end{equation*}
$$

Substitute $\alpha$ (the rational number) where $n$ (the integer number) appears from equation 2.3 to create equation 2.4 shown below.

$$
\begin{equation*}
f^{a}(x)=D^{a} e^{p x}=p^{a} * e^{p x} \tag{2.4}
\end{equation*}
$$

$\mathrm{D}^{\alpha}$ represents any value for $\alpha$-integer, rational, irrational, or complex. For example, dreplace $\alpha$ with the rational number $1 / 2$ resulting in the $1 / 2$ order derivative of the exponential function as shown below in equation 2.5 .

$$
\begin{equation*}
f^{\frac{1}{2}}(x)=D^{\frac{1}{2}} e^{p x}=\sqrt{p} * e^{p x} \tag{2.5}
\end{equation*}
$$

A positive real $\alpha$ represents a derivative of the function and a negative $\alpha$ represents an integral of the function for the example above (Kleinz \& Osler, 2000). Note, fractional order derivatives use previous information to converge to the solution; whereas, integer order derivatives are defined completely at a point.

### 2.2.2 Fractional Derivative of Trigonometric Functions

Choudhuri and French (2018) derive the general form of the fractional order derivative of trigonometric functions sine and cosine using Euler's expression shown below in equation 2.6.

$$
\begin{equation*}
e^{j x}=\cos (x)+j * \sin (x) \tag{2.6}
\end{equation*}
$$

Substitute equation 2.6 into equation 2.1 to obtain the general form of the fractional order derivative of a trigonometric function shown below as equation 2.7.

$$
\begin{equation*}
D^{a} * e^{j x}=j^{a} * e^{j x}=e^{j\left(x+\frac{\pi a}{2}\right)}=\cos \left(x+\frac{\pi a}{2}\right)+j * \sin \left(x+\frac{\pi a}{2}\right) \tag{2.7}
\end{equation*}
$$

### 2.2.3 Fractional Derivative of Polynomial Functions

Kleinz and Osler (2000) provide the generalized derivative of a polynomial in equation 2.8 below.

$$
\begin{equation*}
D^{n} x^{p}=\frac{p(p-1)(p-2) \ldots(p-n+1)(p-n)(p-n-1) \ldots 1}{(p-n)(p-n-1) \ldots 1} x^{p-n}=\frac{p!}{(p-n)!} x^{p-n} \tag{2.8}
\end{equation*}
$$

Equation 2.8 is the integer expression for $D^{n} x^{p}$ and to replace the positive integer $n$ by the arbitrary number $\alpha$, the gamma function must be used. The gamma function, introduced by Euler in the $18^{\text {th }}$ century, provides meaning to $p!$ and $(p-n)!$ when $p$ and $n$ are not integers. The gamma function represented by equation 2.9 satisfies the property shown below in equation 2.10 (Podlubny, 1999).

$$
\begin{gather*}
\Gamma(x)=\int_{0}^{\infty} e^{-t} t^{x-1} d t  \tag{2.9}\\
\Gamma(x+1)=x \Gamma(x) \tag{2.10}
\end{gather*}
$$

Equation 2.8 is then rewritten in the following form since integer $n$ is replaced by the non-natural number $\alpha$ as shown in equation 2.11 below.

$$
\begin{equation*}
D^{a} x^{p}=\frac{\Gamma(p+1)}{\Gamma(p-a+1)} x^{p-a} \tag{2.11}
\end{equation*}
$$

The concept of fractional derivatives is extended to cover a variety of functions by using a Taylor series in terms of $x$ shown below in equation 2.12.

$$
\begin{equation*}
f(x)=\sum_{n=0}^{\infty} a_{n} x^{n} \tag{2.12}
\end{equation*}
$$

Differentiate equation 2.12 term by term resulting in equation 2.13 shown below.

$$
\begin{equation*}
D^{a} f(x)=\sum_{n=0}^{\infty} a_{n} D^{a} x^{n}=\sum_{n=0}^{\infty} a_{n} \frac{\Gamma(n+1)}{\Gamma(n-a+1)} x^{n-a} \tag{2.13}
\end{equation*}
$$

Equation 2.13 is the generalized definition of the fractional derivative (Kleinz \& Osler, 2000).

### 2.2.4 Fractional Integrals

Kleinz and Osler (2000) provide the first and second definite integer order integral of a function as shown in equation 2.14 and equation 2.15 below.

$$
\begin{align*}
& D^{-1} f(x)=\int_{0}^{x} f(t) d t  \tag{2.14}\\
& D^{-2} f(x)=\int_{0}^{x} \int_{0}^{t_{2}} f\left(t_{1}\right) d t_{1} d t_{2} \tag{2.15}
\end{align*}
$$

The left-hand plot found in Figure 2 illustrates the area of integration represented by equation 2.15 from above. The right-hand plot found in Figure 2.1 illustrates how the area of
integration has changed direction after rearranging the order of integration as shown below in equation 2.16 .

$$
\begin{equation*}
D^{-2} f(x)=\int_{0}^{x} \int_{t_{1}}^{x} f\left(t_{1}\right) d t_{2} d t_{1} \tag{2.16}
\end{equation*}
$$

Figure 2.1 Illustration of the Lebesgue integral and Riemann integral, respectively (Kleinz \& Osler, 2000).

Equation 2.16 is changed by moving $f\left(t_{1}\right)$ outside the inner integral since $f\left(t_{1}\right)$ is not a function of $t_{2}$ in this example resulting in equation 2.17 shown below.

$$
\begin{equation*}
D^{-2} f(x)=\int_{0}^{x} f(t)(x-t) d t \tag{2.17}
\end{equation*}
$$

The same procedure is performed for the third and fourth integer-based integrals shown in equation 2.18 and equation 2.19 below.

$$
\begin{align*}
& D^{-3} f(x)=\frac{1}{2} \int_{0}^{x} f(t)(x-t)^{2} d t  \tag{2.18}\\
& D^{-4} f(x)=\frac{1}{2 * 3} \int_{0}^{x} f(t)(x-t)^{3} d t \tag{2.19}
\end{align*}
$$

Considering equations 2.17 to 2.19 , the generalized definition of the integer order integral is shown in equation 2.20 below.

$$
\begin{equation*}
D^{-n} f(x)=\frac{1}{(n-1)!} \int_{0}^{x} f(t)(x-t)^{n-1} d t \tag{2.20}
\end{equation*}
$$

Replace the $-n$ term with the arbitrary $\alpha$ term and the factorial with the gamma function to produce the definition of the Riemann-Liouville fractional order integral. The Riemann-Liouville
fractional integral expression shown below in equation 2.21 is derived from the Laplace transform methods (Magin, 2006).

$$
\begin{equation*}
{ }_{b} D_{x}^{a} f(x)=\frac{1}{\Gamma(-a)} \int_{b}^{x} \frac{f(t) d t}{(x-t)^{a+1}} \tag{2.21}
\end{equation*}
$$

The fractional derivative symbol $D^{a}$ represents positive and negative values for $\alpha$. The integral is improper if $\alpha>-1$ because as $t \rightarrow x, x-t \rightarrow 0$ causing the integral to diverge for every $a \geq 0$. The improper integral converges whenever $-1<a<0$ indicating the $\alpha$ term must be negative. Only negative values for $\alpha$ must be used in the example above to consider equation 2.21 as a definition for the fractional integral which is why limits are included (Kleinz \& Osler, 2000). The following section outlines how the limit resolves the inherent contradiction found in the definition of fractional calculus and provides methods for solving fractional order differential equations.

### 2.2.5 Solving Fractional Order Differential Equations

Integer order integrals are expected to have limits hence fractional order integrals are also expected to have limits. Integer-based derivatives are not governed by limits; however, fractional order derivatives surprisingly must have limits. Why must the limit be included for fractional order derivatives if not included for integer order derivatives? Recall equation 2.4 from above containing the fractional derivative for the exponential function. Substitute the fractional derivative of the exponential function from equation 2.4 into the Taylor Series from equation 2.13 resulting in equation 2.22 shown below (Kleinz \& Osler, 2000).

$$
\begin{equation*}
D^{a} e^{x}=\sum_{n=0}^{\infty} \frac{1}{n!} x^{n}=\sum_{n=0}^{\infty} \frac{x^{n-a}}{\Gamma(n-a+1)} \tag{2.22}
\end{equation*}
$$

The right side of equation 2.22 from above is equivalent to the Taylor series for $e^{x}$ only when $\alpha$ is an integer. The case in which $\alpha$ is fractional results in two different functions. The expression for the fractional derivative of the exponential function from equation 2.4 is inconsistent with the expression for the fractional derivative of the power function from equation 2.13 since two different limits are being used (Choudhuri \& French, 2018).

Notice the fractional integral for an exponential function in equation 2.23 shown below.

$$
\begin{equation*}
{ }_{b} D_{x}^{-1} e^{a x}=\int_{b}^{x} e^{a x} d x=\frac{1}{a} e^{a x}-\frac{1}{a} e^{a b} \tag{2.23}
\end{equation*}
$$

The limit is incorporated to satisfy equation 2.23 from above. The term $\frac{1}{a} e^{a b}=0$ when $\alpha$ is positive and the lower limit $b$ is equal to $-\infty$ represented by equation 2.24 below.

$$
\begin{equation*}
{ }_{-\infty} D_{x}^{a} e^{a x}=a^{a} e^{a x} \tag{2.24}
\end{equation*}
$$

The fractional integral with the lower limit equal to $-\infty$ is referred to as the Weyl fractional derivative as seen in equation 2.24 above. The Weyl fractional derivative equation is derived from the Riemann-Liouville fractional order integral expression hence equation 2.25 below (Choudhuri \& French, 2018).

$$
\begin{equation*}
{ }_{-\infty} D_{x}^{a} f(x)=\frac{1}{\Gamma(-a)} \int_{b}^{x} \frac{f(t) d t}{(x-t)^{a+1}} \tag{2.25}
\end{equation*}
$$

### 2.3 Dynamics

### 2.3.1 Spring-damped System

Dynamics is defined as the branch of mechanics concerned with bodies in motion. The following section explains how the equations of motion for a single degree of freedom system govern the dynamics for the experimental apparatus by using the ideal mass-spring-damped system for the example. The single degree of freedom mass-spring-damped system used in the following experiment captures the basic behavior of vibrating structures since all structures have mass and stiffness. Proportional damping closely resembles the behavior of vibrating structures and simplifies the mathematical models used in the experiment. Other damping models exist but add complexity to the mathematical models compared to proportional damping. Replacing the proportional damper with the fractional damper presents the possibility of modeling more complicated dynamic behavior. Figure 2.2 shown below illustrates the ideal mass-spring-damped system.

Figure 2.2 Ideal mass-spring-damped system (Jones, 2001).

The equation of motion for the ideal mass-spring-damped system with one degree of freedom is written as:

$$
\begin{equation*}
m \frac{d^{2} x(t)}{d t^{2}}+c \frac{d x(t)}{d t}+k x(t)=f(t) \tag{2.26}
\end{equation*}
$$

where $m$ is the mass, $k$ is the spring stiffness, and $c$ is the damping coefficient. Equation 2.26 indicates the applied force $f(t)$ is perfectly counteracted by the sum of the inertial force $m \frac{d^{2} x(t)}{d t^{2}}$, the stiffness force $c \frac{d x(t)}{d t}$, and the damping force $k x(t)$.

The motion equation from above is rewritten considering the free response characteristic of the system meaning that the external force on the system is equal to zero as shown below in equation 2.27 (Jones, 2001).

$$
\begin{equation*}
m \frac{d^{2} x(t)}{d t^{2}}+c \frac{d x(t)}{d t}+k x(t)=0 \tag{2.27}
\end{equation*}
$$

Choudhuri and French (2018) provide the example in which $x(t)=A e^{\lambda t}$ is the characteristic function hence equation 2.28 and equation 2.29 below.

$$
\begin{gather*}
\left(\lambda^{2} m+\lambda c+k\right) A e^{\lambda t}=0 \Rightarrow \lambda^{2} m+\lambda c+k=0  \tag{2.28}\\
\lambda_{1,2}=\left(-\zeta \pm \sqrt{\zeta^{2}-1}\right) \sqrt{\frac{k}{m}} \tag{2.29}
\end{gather*}
$$

The first and the second order eigenvalues are indicated by $\lambda_{1,2}$ from equation 2.29.
Eigenvalues, in context of the proposed experimental study, are numbers that lie on the complex plane and correspond to the roots of the natural frequencies of the system (Howle \& Trefethen, 2001). The damping ratio, represented by $\zeta$, is a dimensionless measure describing the oscillatory decay of the system. The expression for the damping ratio is shown in equation 2.30 below.

$$
\begin{equation*}
\zeta=\frac{c}{2 \sqrt{k m}} \tag{2.30}
\end{equation*}
$$

The damping ratio is expressed as a fraction of critical damping. Critically damping indicates that the system returns to equilibrium without oscillating. The experimental apparatus was designed as an underdamped system meaning the oscillatory decay is exponential.

### 2.3.2 Underdamped

The system is classified as underdamped when the damping ratio is $0<\zeta<1$. The roots of the characteristic function from equation 2.28 above are calculated based on the resonant frequency of the system shown in equation 2.31 below:

$$
\begin{equation*}
\lambda_{1,2}=-\zeta \omega_{n} \pm i \omega_{d} \tag{2.31}
\end{equation*}
$$

where $\omega_{n}=\sqrt{\frac{k}{m}}$ and $\omega_{d}=\omega_{n} \sqrt{1-\zeta^{2}}$ for the underdamped case. Figure 2.4 graphically illustrates the underdamped behavior.

Figure 2.3 Graph of the underdamped system (Mathworks, 2015).

### 2.4 Fluid Mechanics of the Rotating Disk

### 2.4.1 Boundary Layer Conditions

The fluid mechanics of the rotating disk are explained in the following section to provide understanding of the boundary layer formation in the proposed experiment. Cham and Head (1969) determined the distribution of the azimuthal and radial velocity field existing within the turbulent boundary layer on a rotating disk as illustrated by Figure 2.4. The red lines model the azimuthal (meaning in the $\Omega$-direction) velocity profiles corresponding to the theoretical laminar flow, the solid black lines model the measured velocity profiles, and the dashed black line models the boundary layer thickness. The azimuthal velocity at the outer part of the boundary layer is less than $20 \%$ of the velocity of the disk at the same radius. The measured data starts departing from the theoretical laminar flow model for Reynolds values above $R=550$ (Imayama, Lingwood, \& Alfredsson, 2014).

Figure 2.4 Three-dimensional boundary layer formation on the disk (Choudhuri \& French, 2018).

The viscous length scale increases proportionately to the radius for a given Reynolds number as shown in the equation below:

$$
\begin{equation*}
l_{*}=\frac{v}{v_{\tau}}=\frac{v}{\Omega_{z} r} \sqrt{\frac{2}{c_{f}}}=R e^{-2} r \sqrt{\frac{2}{c_{f}}} \tag{2.32}
\end{equation*}
$$

where the friction velocity $v_{\tau}=\sqrt{\frac{\tau_{\omega, \theta}}{\rho}}$, the wall shear stress in the azimuthal direction $\tau_{\omega, \theta}$, and the fluid density $\rho$. The skin friction coefficient $c_{f}=\frac{2 v_{\tau}^{2}}{\left(\Omega_{Z} r\right)^{2}}$ is a decreasing function of the Reynolds number (Imayama, Lingwood, \& Alfredsson, 2014).

The Navier-Stokes differential equation is used to model the flow of incompressible fluids. Choudhuri and French (2018) derived the general form of the Navier-Stokes equation in cylindrical coordinates to obtain the system of fractional order partial differential equations in which model the fluid flow in the proposed experiment as shown in equations 2.33 to 2.35 below.

$$
\begin{align*}
& \rho\left(\frac{d v_{r}}{d t}+v_{r} \frac{d v_{r}}{d r}+v_{\theta} \frac{d v_{r}}{d \theta}-\frac{v_{\theta}^{2}}{r}+v_{z} \frac{d v_{r}}{d z}\right)= \\
& \rho g_{r}-\frac{d P}{d r}+\mu\left(\frac{d}{d r}\left(\frac{1}{r} * \frac{d}{d r}\left(r v_{r}\right)\right)+\frac{1}{r^{2}} * \frac{d^{2} v_{r}}{d \theta^{2}}-\frac{2}{r^{2}} * \frac{d v_{r}}{d \theta}+\frac{d^{2} v_{r}}{d z^{2}}\right)  \tag{2.33}\\
& \rho\left(\frac{d v_{\theta}}{d t}+v_{r} \frac{d v_{\theta}}{d r}+\frac{v_{\theta}}{r} * \frac{d v_{\theta}}{d \theta}+\frac{v_{r} v_{\theta}}{r}+v_{z} \frac{d v_{\theta}}{d z}\right)= \\
& \rho g_{\theta}-\frac{1}{r} * \frac{d P}{d \theta}+\mu\left(\frac{d}{d r}\left(\frac{1}{r} * \frac{d}{d r}\left(r v_{\theta}\right)\right)+\frac{1}{r^{2}} * \frac{d^{2} v_{\theta}}{d \theta^{2}}-\frac{2}{r^{2}} * \frac{d v_{\theta}}{d \theta}+\frac{d^{2} v_{\theta}}{d z^{2}}\right)  \tag{2.34}\\
& \rho\left(\frac{d v_{z}}{d t}+v_{r} \frac{d v_{z}}{d r}+\frac{v_{\theta}}{r} * \frac{d v_{z}}{d \theta}+v_{z} \frac{d v_{z}}{d z}\right)= \\
& \rho g_{z}-\frac{d P}{d z}+\mu\left(\frac{1}{r} * \frac{d}{d r}\left(r \frac{d v_{z}}{d r}\right)+\frac{1}{r^{2}} * \frac{d^{2} v_{z}}{d \theta^{2}}+\frac{d^{2} v_{z}}{d z^{2}}\right) \tag{2.35}
\end{align*}
$$

The continuity equation expresses conservation of mass in the system where the fluid is flowing. The continuity equation and the expression for the shear stress acting on the surface of the disk, shown below as equations 2.36 and 2.37 respectively, are applied to solve the fractional differential equations derived from the Navier-Stokes equation (Choudhuri \& French, 2018).

$$
\begin{gather*}
\frac{1}{r} * \frac{d}{d r}\left(r v_{r}\right)+\frac{1}{r} * \frac{d v_{\theta}}{d \theta}+\frac{d v_{z}}{d z}=0  \tag{2.36}\\
\tau_{\theta}=-\mu\left[2\left(\frac{1}{r} * \frac{d v_{\theta}}{d \theta}+\frac{v_{r}}{r}\right)-\frac{2}{3}\left(\frac{1}{r} * \frac{d}{d r}\left(r v_{r}\right)+\frac{1}{r} * \frac{v_{\theta}}{d \theta}+\frac{d v_{z}}{d z}\right)\right] \tag{2.37}
\end{gather*}
$$

### 2.5 Seminal Theoretical Proposal

Torvik and Bagley (1984) originally proposed the application of fractional calculus methods to model the oscillating dynamic behavior of the large plate fixed to a massless spring submerged in a homogeneous fluid illustrated in Figure 2.8 below.

Figure 2.5 Plate with surface area A and mass $m$ is connected to a massless spring with a spring constant k (Magin, 2006).

Oscillatory motion is initiated by the force $f(t)$ applied to the plate in the x-direction. Magin (2006) explains how the application of Newton's second law to the system from Figure 9 yields the following fractional order differential equation:

$$
\begin{equation*}
m \frac{d^{2} x(t)}{d t^{2}}+k x(t)+2 A \sqrt{\rho \mu} \frac{d^{\frac{3}{2} x(t)}}{d t^{\frac{3}{2}}}=f(t) \tag{2.38}
\end{equation*}
$$

where $m$ is the mass of the plate, $k$ is the spring constant, $A$ is the surface area of the plate, $\rho$ is the fluid density, $\mu$ is the fluid viscosity, and $f(t)$ is the force applied to the plate in the $\mathrm{x}-$ direction. The following experiment used the oscillating disk to eliminate leading and trailing edges thus simplifying the mathematical models in comparison to Torvik and Bagley's experiment where a rectangular plate was used.

The general form of Green's function appears in equation 2.39 below (Podlubny, 1999).

$$
\begin{equation*}
a_{0} D_{t}^{\beta} y(t)+b_{0} D_{t}^{a} y(t)+c y(t)=f(t) \tag{2.39}
\end{equation*}
$$

The Green's function must be applied to equation 2.39 from above to solve the fractional differential equation with constant coefficients and initial conditions. The analytical solution of equation 2.40 appears below (Podlubny, 1999):

$$
\begin{equation*}
y(t)=\int_{0}^{t} G_{3}(t-\tau) f(\tau) d \tau \tag{2.40}
\end{equation*}
$$

where $G_{3}=\frac{1}{A} \sum_{k=0}^{\infty} \frac{(-1)^{k}}{k!}\left(\frac{C}{A}\right)^{k} t^{2 k+1} E_{\frac{1}{2}, 2+\frac{3 k}{2}}^{k}\left(-\frac{B}{A} \sqrt{t}\right), E_{\lambda, \mu}^{k}=\frac{d^{k}}{d y^{k}} E_{\lambda, \mu}(y)=\sum_{j=0}^{\infty} \frac{(j+k)!y^{j}}{j!\Gamma(\lambda j+\lambda k+\mu)}$, and $k=0,1,2, \ldots$

### 2.6 Applications

Fractional calculus models a variety of complex dynamic systems more accurately compared to traditional calculus. Recent development for applications of fractional order calculus include but is not limited to fluid mechanics, electrical circuits, heat transfer, signal processing, chemical processes, bioengineering, and automatic control. Torvik and Bagley (1984) experimentally validated the accuracy of the fractional order calculus model by the finite analysis of transient motion in complex viscoelastically-damped structures. The application of fractional calculus to model Proportional Integral Derivative (PID) controllers improved system precision, efficiency, and overall quality of industrial process control compared to the integer order model (Tepljakov, 2017). Ultracapacitors are electrical devices used to store and dissipate energy in applications where a high current is supplied for brief time intervals. The study conducted by Dzieliński, Sarwas, and Sierociuk (2011) revealed how ultracapacitor frequency domain models are intrinsically fractional order. Richard Magin (2006) provides compelling results in which describe the viscoelasticity of human lung tissue using pulmonary impedance models of fractional order.

### 2.7 Chapter Summary

Fractional calculus-the method of integration and differentiation to an arbitrary, noninteger order-was conceived through combined efforts nearly the same time as integer order calculus in 1695 (Kulish \& Lage, 2002). The fractional order notation $\frac{d^{\frac{1}{2}} f(x)}{d x^{\frac{1}{2}}}$ or $D^{\frac{1}{2}} f(x)$ is now familiar considering the fundamental theories and basic operations associated with fractional
calculus methods were explained in detail. Torvik and Bagley (1984) originally proposed the application of fractional calculus methods to model the dynamic behavior of the rectangular plate fixed to a massless spring submerged in a homogeneous fluid. The following experiment incorporated a disk to eliminate the leading and trailing edges thus simplifying the mathematical models. The motivation for the proposed research is derived directly from previous efforts of Choudhuri and French (2018) in which the dynamics of an oscillating cylinder were modeled and experimentally validated to be of fractional order.

## CHAPTER 3. RESEARCH METHODOLOGY

### 3.1 Research Approach and Hypotheses

Can the angular position of a disk oscillating in a homogeneous fluid be calculated using a fractional order mathematical model? Does the fractional order model calculating the angular position of a disk oscillating in a homogeneous fluid yield a more accurate solution than the integer order model? The purpose of this study is to experimentally validate the fractional order model of the proposed dynamic system with a quantitative comparison between the fractional and integer order models.

The margins of error must be considered to make such a comparison for each model. The fractional order model, integer order model, and quantitative comparison to determine the accuracy of each model are the key deliverables of this study. Frictional losses in the bearings, static and dynamic alignment of the components, and rotational forces causing the support structure to flex are key factors affecting the error in the experiment. The hypotheses tested during the experiment are listed as follows:

- $\mathbf{H}_{\mathbf{0}}$ : The fractional order model of the angular position of the oscillating disk produces less error than the integer order model when comparing the mathematical models to the experimental data.
- $\mathbf{H}_{\mathbf{a}}$ : The integer order model of the angular position of the oscillating disk produces less error than the fractional order model when comparing the mathematical models to the experimental data.

### 3.2 Theoretical Models

### 3.2.1 Integer Order Model

The proposed research compares the integer-based and fractional-based models to determine if the dynamics of the system are of inherent fractional order. The free body diagram for the integer order theoretical model is illustrated by Figure 3.1 below.

Figure 3.1 The free body diagram of the oscillating disk for the integer order model (Choudhuri \& French, 2018).

The integer order equation of motion for the system appears in equation 3.1 below.

$$
\begin{equation*}
I \frac{d^{2} \theta}{d t}+C \frac{d \theta}{d t}+K \theta=f(t) \tag{3.1}
\end{equation*}
$$

The area moment of inertia for the cylinder is calculated using equation 3.2 and the spring constant was calculated using equation 3.3.

$$
\begin{align*}
& I=\frac{\pi \rho h}{2}\left(r_{\text {outer }}^{4}-r_{\text {inner }}^{4}\right)  \tag{3.2}\\
& K=\frac{G \pi D_{\text {rod }}^{4}}{32 L} \tag{3.3}
\end{align*}
$$

The general integer order equation for the dynamic system in free oscillation appears in equation 3.2 below:

$$
\begin{equation*}
\theta=A \sin (\omega t+\phi) e^{-\sigma t} \tag{3.4}
\end{equation*}
$$

where $A$ is the amplitude, $\omega$ is the natural frequency of the system, $\phi$ is the phase difference, and $\sigma$ is the shear stress (Choudhuri \& French, 2018).

### 3.2.2 Fractional Order Model

The free body diagram for the fractional theoretical model used in the experiment is illustrated by Figure 3.2 below.

Figure 3.2 The free body diagram of the oscillating cylinder with initial boundary conditions for the fractional model (Choudhuri \& French, 2018).

The torsion spring with the spring stiffness $K$ was assumed to be massless and did not cause complications regarding the fluid mechanics of the system. The disk with mass $M$ and area $S$ was assumed to oscillate in the homogeneous fluid with only one degree of freedom. The BagleyTorvik fractional differential equation was used to compute the numerical solution for the fractional order model as shown in equation 3.3 below:

$$
\begin{gather*}
A y^{\prime \prime}(t)+B_{0} D_{t}^{3 / 2}+C y(t)=f(t)  \tag{3.3}\\
A=M, \quad B=2 \sqrt{\mu \rho}, \quad C=K
\end{gather*}
$$

where the initial conditions were $y(0)=18.9132, y^{\prime}(0)=18.9132, f(t)=0$ (Podlubny, 1999, p. 229). The initial force was zero to simplify the mathematical models approximating the angular position of the oscillating disk.

### 3.3 Related Experiment

Choudhuri and French (2018) conducted the experimental study of fractional calculus to model the dynamics of a cylinder oscillating while submerged in a homogeneous fluid as illustrated in Figure 2.9 below.

Figure 3.3 Experimental setup from previous research (Choudhuri \& French, 2018).

The apparatus illustrated in Figure 3.3 consists of a plastic cylinder made from polyvinyl chloride, an acrylic fish tank, stainless steel shaft, ceramic bearings, steel ball bearing, brazing rod for the spring, camera, and 3D printed material for some of the structural parts. The initial force (spinning force) causes the cylinder to oscillate for 100 seconds before coming to rest again. Testing was conducted in standard temperature and pressure where the cylinder was fully submerged in the homogeneous fluid. The research previously conducted by Choudhuri and French (2018) experimentally validated the fractional order model for the oscillating cylinder submerged in the homogeneous fluid.

### 3.4 Experimental Setup

The experimental apparatus used in this study was derived from the previous experiment conducted by Choudhuri and French (2018) where an oscillating cylinder was used. The experimental apparatus was designed as an underdamped system to satisfy the general integer order equation of a body in free oscillation found in equation 3.4 above. In this experiment, an aluminum disk was used as the body oscillating in the homogeneous fluid and was made from 6061 aluminum. The aluminum disk was machined to have an outer diameter of 9.817 inches, an inner diameter of 0.4985 inches, and a height of 2.424 inches. The flatness and cylindricity geometric tolerances were controlled while machining the aluminum disk to produce a uniform surface finish. The inner diameter through hole tolerances were controlled to ensure a successful shrink fit between the disk and shaft. The uniform surface finish of the disk produced a uniform drag coefficient along the top and bottom surfaces. The precision ground, polished shaft was purchased from McMaster Carr with a diametral tolerance of -0.0002 inches to 0 inches and a straightness tolerance of 0 inches to 0.0048 inches per foot. The shaft was made from 303 stainless steel with a measured diameter of 0.5000 inches. Micrometers and calipers were used to inspect the dimensions of the machined components. The disk and shaft were joined with a shrink fit, and the disk was carefully positioned at half of the height of the tank which was 12 inches from the bottom of the tank. The tolerances of the components were ideal to minimize fluid layer boundary effects incurring around the shaft and maintain the perpendicular alignment required between the disk and the shaft. The disk oscillated about the vertical axis of the shaft where both ends of the shaft were supported by bearings. A short shaft approximately 2 inches in length was cut from the main section of the shaft and fixed into the base of the apparatus. The base was a 3D printed housing designed for the short section of the shaft which was attached to the bottom of the tank with epoxy. The short shaft and main shaft were coupled by the lubricated 0.25 -inch ball bearing. Figure 3.3 is an image of the bottom support where the bottom shaft was coupled to the main shaft with the 0.25 -inch ball bearing. The tank used in the experiment had a 36 -inch diameter with a 24 -inch height.

Figure 3.4 Image of the bottom support.

The upper end of the shaft was machined to allow one end of the music wire to slide inside the pocket. Threaded holes were included for the set screws to fix the end of the wire in place. The radial bearing purchased from Bearing Headquarters Company was pressed onto the upper end of the shaft. Figure 3.4 is an image depicting the radial bearing pressed onto the upper end of the shaft.

Figure 3.5 Radial bearing pressed onto the upper end of the shaft.

The radial bearing was then press-fitted into a 3D printed plate to support and center the vertical alignment of the shaft. The 3D printed plate was fixed to the wooden frame using screws and wing nuts. Figure 3.6 below contains a screenshot of the 3D model illustrating how the bearing plate was fixed to the wooden frame. The music wire with a measured diameter of 0.21875 -inch and a measured length of 28 inches served as the torsional spring. The upper and lower crossbeams of the wooden structure supported the top and bottom ends of the music wire in which both ends were fixed by stainless steel set screws. Figure 3.7 found below contains an image of the experimental setup. Figure 3.8 contains a screenshot of the 3D model of the experimental apparatus.

Figure 3.6 3D model of the bearing plate fixed to the wooden structure.

Figure 3.7 Experimental setup.

Figure 3.8 3D model of the experimental apparatus.

The center axis of the camera lens was constrained to the vertical axis of the shaft to eliminate parallax. The fully threaded rod supporting the tracer extends 12 inches from the threaded hole through the shaft. The threaded rod extending from the shaft was considered as the radius for calibration purposes. The camera was accurately positioned and calibrated by
collecting data in Tracker and generating a plot of the radius versus time. The plot shown in Figure 3.9 below verified the alignment of the center axis of the camera lens to the vertical axis of the shaft by producing a constant value for radius as a function of time.

Figure 3.9 Plot of radius (m) vs. time ( sec ) to verify camera alignment.

### 3.5 Data Acquisition

The experiment was conducted in an environment with standard temperature and pressure. Video data was acquired using a Panasonic LUMIX G7 camera with specifications of 60 frames per second and shutter speed of $1 / 1000$ seconds. The camera was mounted 9 feet and 9 inches from the ground pointed downward to view into the tank. The MP4 file created from the video recording was uploaded into Tracker-an open source physics software. Figure 3.10 contains a screenshot of the Tracker software interface displaying the camera's view from above the apparatus.

Figure 3.10 Tracker software interface.

Using Tracker, the necessary frames of reference and relative positions for the components were created by following the tracer. The tracer was a rectangular piece of white cardboard fixed onto the end of the threaded rod. The black dot was placed in the center of the white cardboard rectangle allowing the software to accurately track the radial position of the oscillating disk. Figure 3.11 contains a screenshot of Tracker recording the position of the black dot.

Figure 3.11 Tracker recording the position of the black dot.

The threaded hole was machined into the shaft to mate with a fully threaded rod supporting the tracer. Plumbing tape was included where the fully threaded rod mated with the shaft to damp the vibrations generated while applying the initial spin force. Figure 3.12 contains an image of the fully threaded rod supporting the tracer used during the experiment.

Figure 3.12 Image of the tracer used for Tracker.

### 3.6 Data Analysis

Tracker software was used to acquire the data and create a text file by exporting to the Notepad application found on the computer. The text file containing the experimental data collected by Tracker was imported to MATLAB using a built-in function and processed to generate the fractional and integer order models. MATLAB produced graphical representations of the integer and fractional order models superimposed on the experimental data plot. The quantitative comparison between graphs determined if the dynamics of the spring-damped oscillating system are considered intrinsically fractional order. The squared difference calculated between the experimental data and the mathematical models was the primary metric to determine error for each model in this study. The more accurate model incurred the least amount of error when compared to the experimental data. Further details regarding error calculations are included in the Results section below.

### 3.7 Threats to Validity

Mechanical and frictional losses were controlled by proper alignment between components. Tight machining tolerances were maintained throughout the development of the experimental apparatus to ensure perpendicularity between the stainless steel shaft and the aluminum disk. Uneven loading because of misalignment between the aluminum disk and stainless steel introduces frictional forces to the system. The system is assumed to be in free response meaning at $\mathrm{t}=0$ seconds the input force is $f(t)=0$. Although the system is assumed to be in free response, the input spin force needed to initiate oscillation potentially introduces uneven loading considering the input spin force is performed by hand motion. Proper alignment of the components was also verified by using a level to ensure the ground was not sloped where the apparatus was placed. Additionally, the bottom of the tank was inspected to ensure that the 3D-printed bottom support was level. The torsion spring was replaced every trial to eliminate mechanical losses caused by rotational fatigue stress and to minimize variation in the spring stiffness since the mathematical models use constant coefficients to approximate the angular position of the oscillating disk. Rotational angles of 30 degrees or larger resulted in plastic deformation of the torsion spring, and the wooden support structure flexed while the angles of rotation exceeded 30 degrees. The center axis of the camera lens was constrained to the vertical axis of the stainless steel shaft to minimize parallax and a plot of radius versus time was created to calibrate the camera position as seen in Figure 3.9 above. Quality inspections of component dimensions were accomplished using measurement equipment such as micrometers and calipers. All components of the experimental apparatus were visually inspected for defects before use.

## CHAPTER 4. RESULTS

### 4.1 Experimental Data

The experimental apparatus was designed to be an underdamped system; however, the oscillatory decay does not perfectly mimic exponential decay. The input spin force is performed by hand motion and suspected to cause uneven loading resulting in frictional loss until the system balances and is in free response oscillation. The fatigue stresses acting on the torsion spring are suspected to cause plastic deformation after 30-40 oscillations and are suspected to be the source of difference after $t=15$ seconds. The following sections explain further details regarding the discrepancies of the data and elaborate on the quantitative comparison between the mathematical models and the experimental data. The experimental data is graphically represented in Figure 4.1 below and the table containing the experimental data is in Appendix A located at the end of the document.

Figure 4.1 Graph of the experimental data from MATLAB.

### 4.2 Comparison of Theoretical Models

The integer and fractional order models were computed using finite difference approximation methods which are used to find numerical solutions of differential equations. Figure 4.2 and Figure 4.3 are graphical representations of the integer and fractional order models, respectively. Figure 4.4 graphically compares the local maxima of the experimental data and integer and fractional order models.

The local maxima for each was calculated using the built-in MATLAB function named findpeaks which returns a vector with the local maxima of the input signal. Figure 4.5 and Figure 4.6 graphically illustrates the squared difference between the integer model versus the experimental data and the fractional model versus the experimental data, respectively. Equation 4.1 below represents how the squared difference was calculated for the quantitative comparison between the models and experimental data.

$$
\begin{equation*}
\text { Squared Difference }=\left(\theta_{\text {calc }}-\theta_{\text {exp }}\right)^{2} \tag{4.1}
\end{equation*}
$$

Referring to Figure 4.5 and Figure 4.6, the largest squared difference calculated was 7.77 degrees squared between the integer order model and the experimental data and 7.849 degrees squared between the fractional order model and the experimental data. The largest squared difference occurred at $\mathrm{t}=0$ seconds. The input spin force is performed by hand motion and suspected to cause uneven loading resulting in frictional loss until the system balances and is in free response oscillation. The squared difference between the mathematical models and the experimental data approaches zero from $t=5$ seconds to $t=15$ seconds. After $t=15$ seconds, the largest squared difference calculated between the experimental data and the integer and fractional models is 2.00 degrees squared and 1.50 degrees squared, respectively. The fatigue stresses acting on the torsion spring are suspected to cause plastic deformation after 30-40 oscillations and are suspected to be the source of difference after $t=15$ seconds.

Figure 4.6 Plot for the squared difference between fractional model and experimental data.

## CHAPTER 5. SUMMARY, CONCLUSION, AND RECOMMENDATIONS

The fractional order mathematical model approximated the angular position of the oscillating system using the Bagley and Torvik fractional derivative. The experiment validated the application of fractional order calculus to determine the analytical solution for the differential equations governing the physics of the oscillating system. The graphical comparisons between the experimental data and the integer and fractional order models were illustrated in Figures 4.1 through 4.6. The squared difference calculated between the experimental data and the mathematical models is graphically represented by Figure 4.5 and Figure 4.6 and represented by equation 4.1 above. The largest squared difference calculated was 7.77 degrees squared between the integer order model and the experimental data as shown in Figure 4.5. The largest squared difference calculated was 7.849 degrees squared between the fractional order model and the experimental data as shown in Figure 4.6. The largest squared difference occurred at $\mathrm{t}=0$ seconds. The input spin force at $\mathrm{t}=0$ seconds is performed by hand motion and suspected to cause uneven loading resulting in frictional loss. The squared difference between the mathematical models and the experimental data approaches zero from $t=5$ seconds to $t=15$ seconds as shown in Figures 4.5 and 4.6. After $\mathrm{t}=15$ seconds, the largest squared difference calculated between the experimental data and the integer and fractional models is 2.00 degrees squared and 1.50 degrees squared, respectively. The fatigue stresses acting on the torsion spring are suspected to cause plastic deformation after 30-40 oscillations and are assumed to be the source of error after $\mathrm{t}=15$ seconds.

The experiment conducted for the mentioned study has improvements to be made for future efforts. Magnetic or pneumatic bearings could be used to further reduce mechanical friction. Angular displacement was limited during the experiment to 20 degrees or less to prevent flexing of the wooden structure. Although the system is assumed to be in free response, the input spin force is performed by hand motion and potentially causes uneven loading resulting in frictional losses. The input spin force should be applied by a known force acting in a known direction at a known angle to minimize error at $\mathrm{t}=0$ seconds. A fully metal support structure with welded joints is recommended to increase the angular displacement in later experiments and minimize the stresses in supporting components such as the set screws, wooden support structure, and the steel nails within the wooden support structure. The experiment conducted in this study used
purified water, but other fluids can be used to observe the differences in the mathematical models by changing fluid density and viscosity.
