

PRODUCTION OF LAMBDA\_C BARYONS IN  
PROTON-PROTON AND LEAD-LEAD COLLISIONS AT 5.02  
TEV WITH CMS

by

Rui Xiao

A Dissertation

*Submitted to the Faculty of Purdue University*

*In Partial Fulfillment of the Requirements for the degree of*

Doctor of Philosophy

Dr. Gabor Csathy

I am open to everything. When you  
start to criticize the times you live in,  
your time is over.

---

Karl Lagerfeld

Even pigs can fly when placed against  
the wind.

---

Jun Lei

## ACKNOWLEDGMENTS

The work in this thesis could not be possible without the great assistance and support from my family, my advisor, professors, colleagues and friends. I am fortunate to have these amazing people on my journey towards the doctoral degree.

First, I would like to thank my parents and my boyfriend for their support, encourage, love and understanding. My parents, Yuhe Xiao and Ying Gao, have always been supporting my interest, providing me both financial and emotional assistance during my graduate study. My boyfriend, Shengdong Liu, has been extremely patient and unconditionally supportive for the past six and half years.

Second, I would like to express my sincere gratitude to my advisor Prof. Wei Xie for his continuous support and guidance with my research over years. Prof. Xie has taught me what is the most important character to be a physicist, how to shorten the learning curve, how to reduce the systematic uncertainties, and how to overcome the difficulties with persistent effort and inspiring ideas. I would like to thank Prof. Fuqiang Wang for his helpful advice on my research. I would like to thank Prof. Denes Molnar for his explanations and discussion on theory models related to my research and optimizing my algorithm. I would like to thank Prof. Martin Kruczenski for serving as my thesis committee.

Besides my thesis committee, I would like to thank the graduate and postdoctoral group members: Jian Sun, Cheng-Chieh Peng, Hao Qiu, Liang He, Jie Zhao, Terrence Edmonds, Liang Zhang, An Gu, Yicheng Feng, Soumik Chandra, Han-Sheng Li, Milan Stojanovic. They have made the office hours enjoyable and provided daily discussion. I would like to thank Jian Sun, Cheng-Chieh Peng and Hao Qiu for teaching me the CMS software, programming and providing help at the beginning of my studies, as well as Soumik and Milan for contributing to part of the work in this thesis. I also would like to thank all my other friends at Purdue for making my PhD life colorful.

I would like to thank the CMS collaborators from other institutions, who helped to polish the projects presented in this thesis: Jing Wang, Kevin Matthew Stenson, George Stewart Stephans, Emilien Chapon, Yen-Jie Lee and Camelia Mironov. At last, I would like to acknowledge the people, who were involved in the LHC operation, CMS data taking,

software development, and software maintenance. Without their effort, there would not be the high quality data, with which my thesis work is performed.

# TABLE OF CONTENTS

LIST OF TABLES . . . . .	8
LIST OF FIGURES . . . . .	10
ABSTRACT . . . . .	16
1 INTRODUCTION . . . . .	17
1.1 Elementary Particle . . . . .	17
1.2 Quantum Chromodynamics . . . . .	17
1.2.1 Lattice Quantum Chromodynamics . . . . .	19
1.3 Quark Gluon Plasma . . . . .	19
1.3.1 Parton Energy Loss . . . . .	21
1.4 Heavy Ion Collisions . . . . .	22
1.4.1 Centrality Reconstruction And Calibration . . . . .	22
1.5 Open Heavy Flavor Study In Heavy Ion Collisions . . . . .	24
1.6 Event Simulation . . . . .	26
1.6.1 PYTHIA8 Event Generator . . . . .	26
2 THE CMS DETECTOR . . . . .	27
2.1 The Inner Tracking System . . . . .	27
2.2 Hadron Forward Calorimeter . . . . .	30
2.3 The Level-1 And High Level Trigger System . . . . .	32
2.4 The CMS Computing Model . . . . .	33
3 $\Lambda_c^+$ RECONSTRUCTION AND CUT OPTIMIZATION . . . . .	35
3.0.1 $\Lambda_c^+$ Reconstruction . . . . .	35
3.0.2 Cut Optimization . . . . .	36
4 PRODUCTION OF INCLUSIVE $\Lambda_c^+$ IN PP AND PBPB COLLISIONS AT 5.02 TeV WITH 2015 CMS DATA . . . . .	39
4.1 Data Sets And Monte Carlo Simulation . . . . .	39

4.1.1	Signal Monte Carlo . . . . .	39
4.1.2	Event Selection . . . . .	43
4.2	Signal Extraction . . . . .	44
4.3	Acceptance And Efficiency Correction . . . . .	45
4.4	Systematic Uncertainties . . . . .	53
4.5	Results . . . . .	57
5	PRODUCTION OF PROMPT $\Lambda_c^+$ IN PP AND PBPB COLLISIONS AT 5.02 TEV WITH 2017 AND 2018 CMS DATA . . . . .	66
5.1	Data Sets And Monte Carlo Simulation . . . . .	66
5.1.1	Event Selection . . . . .	67
5.2	Signal Extraction . . . . .	68
5.3	Prompt $\Lambda_c^+$ Extraction by DCA Fit . . . . .	68
5.4	Acceptance And Efficiency Correction . . . . .	78
5.5	Systematic Uncertainties . . . . .	79
5.6	Results . . . . .	82

## LIST OF TABLES

4.1	CMS 2015 Datasets Used For Inclusive $\Lambda_c^+$ Production Analysis. . . . .	39
4.2	$\Lambda_c^+$ $p_T$ Threshold, Number Of Output Events And $\hat{P}_T$ Threshold For Simulation Samples For Inclusive $\Lambda_c^+$ Analysis In Both pp And PbPb Collisions. . . . .	42
4.3	Summary Of HLT Paths Used In The 2015 pp And PbPb Analysis . . . . .	43
4.4	Track Selection Criteria Applied In The 2015 pp And PbPb HLT Tracking. . . .	43
4.5	Summary Of The $\langle N_{\text{coll}} \rangle$ , $\langle T_{\text{AA}} \rangle$ , And $\langle N_{\text{part}} \rangle$ Values For Three PbPb Centrality Ranges At 5.02 TeV. . . . .	57
4.6	Summary Of Relative Systematic Uncertainties Of Inclusive $\Lambda_c^+$ Cross Section In pp Collisions At 5.02 TeV With CMS 2015 Data. . . . .	58
4.7	Summary Of Relative Systematic Uncertainties Of Inclusive $\Lambda_c^+$ Differential Yield From Data For 5.02 TeV PbPb Collisions With Three Centrality Ranges With CMS 2015 Data. . . . .	58
4.8	Summary Of Relative Systematic Uncertainties From Data For Inclusive $\Lambda_c^+$ $R_{\text{AA}}$ At 5.02 TeV PbPb Collisions For Centrality 0–100%, 0–30% And 30–100% With CMS 2015 Data. . . . .	59
4.9	Summary Of Relative Systematic Uncertainties For The $\Lambda_c^+/D^0$ (Inclusive $\Lambda_c^+$ And Prompt $D^0$ ) Production Ratio In pp Collisions At 5.02 TeV With CMS 2015 Data. . . . .	59
4.10	Summary Of Relative Systematic Uncertainties For The $\Lambda_c^+/D^0$ (Inclusive $\Lambda_c^+$ And Prompt $D^0$ ) Production Ratio In PbPb Collisions At 5.02 TeV In The Centrality Range 0–100% With CMS 2015 Data. . . . .	60
5.1	CMS 2017 And 2018 Data Sets Used In The Prompt $\Lambda_c^+$ Production Analysis. .	66
5.2	This Table Shows All The Fitted Prompt Ratio Got From The Best MC Resolution Scale Factor, The Systematic Uncertainty Due To DCA Fit And Also The Predicted Prompt Ratio From PYTHIA8 And FNOLL In pp Collisions For $p_T$ Bins 3–4 GeV/ $c$ , 15–20 GeV/ $c$ And 20–30 GeV/ $c$ . . . . .	76
5.3	This Table Shows All The Fitted Prompt Ratio Got From The Best MC Resolution Scale Factor And The Systematic Uncertainty Due To DCA Fit In PbPb Collisions In Centrality Class: 0–10% And 0–90%. . . . .	76
5.4	This Table Shows All The Fitted Prompt Ratio Got From The Best MC Resolution Scale Factor And The Systematic Uncertainty Due To DCA Fit In PbPb Collisions In Centrality Class: 10–30%, 30–50% And 50–90%. . . . .	77
5.5	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ Cross Section In pp Collisions At 5.02 TeV With CMS 2017 Data. . . . .	83

5.6	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ Differential Yield In PbPb Collisions At 5.02 TeV For Centrality 0–90% With CMS 2018 Data. . .	83
5.7	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ Differential Yield In PbPb Collisions At 5.02 TeV For Centrality 0–10% With CMS 2018 Data. . .	84
5.8	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ Differential Yield In PbPb Collisions At 5.02 TeV For Centrality 10–30% With CMS 2018 Data. .	84
5.9	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ Differential Yield In PbPb Collisions At 5.02 TeV For Centrality 30–50% With CMS 2018 Data. .	85
5.10	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ Differential Yield In PbPb Collisions At 5.02 TeV For Centrality 50–90% With CMS 2018 Data. .	85
5.11	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ $R_{AA}$ In Centrality Class: 0–90% With CMS 2017/2018 Data. . . . .	86
5.12	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ $R_{AA}$ In Centrality Class: 0–10% With CMS 2017/2018 Data. . . . .	86
5.13	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ $R_{AA}$ In Centrality Class: 10–30% With CMS 2017/2018 Data. . . . .	87
5.14	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ $R_{AA}$ In Centrality Class: 30–50% With CMS 2017/2018 Data. . . . .	87
5.15	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+$ $R_{AA}$ In Centrality Class: 50–90% With CMS 2017/2018 Data. . . . .	88
5.16	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+/D^0$ In pp Collisions At 5.02 TeV. . . . .	88
5.17	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+/D^0$ In PbPb Collisions In Centrality Class 0–90%. . . . .	89
5.18	Summary Of Relative Systematic Uncertainties For Prompt $\Lambda_c^+/D^0$ In PbPb Collisions In Centrality Class 0–10%. . . . .	89

# LIST OF FIGURES

1.1	Elementary Particles Included In The Standard Model. This Figure Is Taken From Wikipedia [6]. . . . .	18
1.2	A Sketch Illustrating The Experimental And Theoretical Exploration Of The QCD Phase Diagram [15]. . . . .	20
1.3	Distribution Of The Sum Of HF $E_T$ For A Large Minimum Bias Event Sample Divided Into Centrality Classes Of PbPb Collisions At 2.76 TeV. Figure Is Taken From Ref. [27]. . . . .	23
2.1	A Schematic Representation Of The CMS Detector With Its Various Subsystems In Retracted Positions (CERN) . . . . .	28
2.2	Schematic View Of The Previous CMS Tracker (Before The End Of 2016), Showing The Nomenclature Used To Identify Different Sections. Each line Represents A Detector Module. Double Lines Indicate Back-to-back Modules Which Deliver Stereo Hits In The Strip Tracker. This Figure Is Taken From Ref. [57]. . . . .	29
2.3	Transverse Impact Parameter Resolution For Muon Tracks As A Function Of The Track Momentum For Different $\eta$ Ranges. The Black Circles Labeled As "Current" Is For The One Before The Upgrade. The Red Triangles Are For The Upgraded Pixel Detector. The Lower Part Of Each Plot Shows The Ratio Of The Previous Detector Resolution To The Upgraded Resolution. (Top-left) $0 < \eta < 1$ ; (Top-right) $1 < \eta < 1.5$ ; (Bottom-left) $1.5 < \eta < 2$ ; (Bottom-right) $2 < \eta < 2.5$ . This Figure Is Taken From Ref. [57]. . . . .	30
2.4	Longitudinal Impact Parameter Resolution For Muon Tracks As A Function Of The Track Momentum For Different $\eta$ Ranges. The Black Circles Labeled As "Current" Is For The One Before The Upgrade. The Red Triangles Are For The Upgraded Pixel Detector. The Lower Part Of Each Plot Shows The Ratio Of The Previous Detector Resolution To The Upgraded Resolution. (Top-left) $0 < \eta < 1$ ; (Top-right) $1 < \eta < 1.5$ ; (Bottom-left) $1.5 < \eta < 2$ ; (Bottom-right) $2 < \eta < 2.5$ . This Figure Is Taken From Ref. [57]. . . . .	31
2.5	(Left) The Cross Sectional View Of The HF Calorimeter. (Right) Transverse Segmentation Of A Single $20^\circ$ Modular Edge Of The HF Detector. Figures Are Taken From Ref. [56]. . . . .	32
2.6	Dataflow Between Different CMS Computing Centers. This Figure Is Taken From Ref. [56]. . . . .	33
3.1	Schematic View Of The $\Lambda_c^+$ Decay Channel Used In This Thesis. . . . .	35
4.1	The Mass Distribution Of Gen-match Signal And The Swapped Component For pp In $p_T = 10\text{--}20$ GeV/ $c$ . The Red Points Are The Gen-matched Signal And The Blue Points Are Swapped Component. . . . .	46

4.2	Double Gaussian Fit For pp Collisions In $p_T = 5\text{--}6$ GeV/ $c$ (Left) And $6\text{--}8$ GeV/ $c$ (Right). In Both Plots, The Blue Line Is The Whole Double Gaussian Fit Function And The Green And Pink Lines Are The Gaussian Fit Function With The Same Mean But Different Widths. . . . .	47
4.3	Double Gaussian Fit For pp Collisions In $p_T = 8\text{--}10$ GeV/ $c$ (Left) And $10\text{--}20$ GeV/ $c$ (Right). In Both Plots, The Blue Line Is The Whole Double Gaussian Fit Function And The Pink Lines Are The Gaussian Fit Function With The Same Mean But Different Widths. . . . .	47
4.4	Double Gaussian Fit For PbPb Collisions In Centrality Range $0\text{--}100\%$ (Left), $0\text{--}30\%$ (Middle) And $30\text{--}100\%$ (Right). . . . .	48
4.5	$\Lambda_c^+$ Signal Extraction In pp Collisions For $p_T$ Ranges: $5\text{--}6$ GeV/ $c$ (Left) And $6\text{--}8$ GeV/ $c$ (Right). The Red Line Is The Function For The Foreground And The Blue Dashed Line Is The Function For The Background. . . . .	48
4.6	$\Lambda_c^+$ Signal Extraction In pp Collisions For $p_T$ Ranges: $8\text{--}10$ GeV/ $c$ (Left) And $10\text{--}20$ GeV/ $c$ (Right). The Red Line Is The Function For The Foreground And The Blue Dashed Line Is The Function For The Background. . . . .	49
4.7	$\Lambda_c^+$ Signal Extraction In PbPb Collisions For $p_T$ Range $10\text{--}20$ GeV/ $c$ In Centrality Class $0\text{--}100\%$ (left), $0\text{--}30\%$ (Middle) And $30\text{--}100\%$ (Right). The Red Line Is The Function For Foreground And The Blue Dashed Line Is The Function For The Background. . . . .	50
4.8	The $\Lambda_c^+$ Acceptance As A Function Of $p_T$ In pp Collision As Well As PbPb In $0\text{--}30\%$ , $0\text{--}100\%$ And $30\text{--}100\%$ Centrality Bins. . . . .	51
4.9	Invariant Yield Of Prompt $\Lambda_c^+$ Derived From $m_T$ Scaling Of Prompt $D^0$ . . . . .	52
4.10	Invariant Yield Of Nonprompt $\Lambda_c^+$ Derived From $m_T$ Scaling Of Nonprompt $D^0$ . . . . .	52
4.11	The $\alpha\epsilon$ In PbPb Of Three Centrality Bins And pp Collisions. The Closed Squares, The Closed Stars And The Closed Circles Represent $\alpha\epsilon$ In PbPb Collisions Of Centrality Range $30\text{--}100\%$ , $0\text{--}30\%$ And $0\text{--}100\%$ , Respectively. The Pink Triangles Represent $\alpha\epsilon$ Of pp Collisions. . . . .	54

- 4.12 The  $p_T$ -differential Cross Sections For Inclusive  $\Lambda_c^+$  Production In pp Collisions And The  $T_{AA}$ -scaled Yields For Three Centrality Regions Of PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The PbPb Data Points Are Shifted In The Horizontal Axis For Clarity. Predictions For pp Collisions Are Displayed For PYTHIA8 With The CUETP8M1 Tune (Open Crosses), PYTHIA8 With Color Reconnection [69] (Open Stars), And GM-VFNS [70] (Open Circles Labeled “JHEP 12 (2017) 021”) Along With Ratios To The Data In The Lower Two Panels. The PYTHIA8 (GM-VFNS) Predictions Are For Inclusive (Prompt)  $\Lambda_c^+$  Production. The Error Bars On The GM-VFNS Prediction Account For The Scale Variation Uncertainty. The Lower Panels Show The Data-to-prediction Ratio For pp Collisions With Inner And Outer Error Bars Corresponding To The Statistical And Total Uncertainty In The Data, Respectively, And The Shaded Box At Unity Indicating The 21% Normalization Uncertainty. The Shaded Boxes In The Bottom Panel Represent The GM-VFNS Uncertainty. This Figure Is Taken From Ref. [1]. 63
- 4.13 The Nuclear Modification Factor  $R_{AA}$  Versus  $\langle N_{part} \rangle$  For Inclusive  $\Lambda_c^+$  Production. The Error Bars Represent The PbPb Yield Statistical Uncertainties. The Boxes At Each Point Include The PbPb Systematic Uncertainties Associated With The Signal Extraction,  $p_T$  Spectrum, Selection Criteria, Track Reconstruction, And  $T_{AA}$ . The Band At Unity Labeled pp Uncertainty Includes These Same Uncertainties For The pp Data (Except For  $T_{AA}$ ) Plus The Uncertainties In pp Yield And Luminosity. The Band At Unity Labeled PbPb Includes The Uncertainty From The Nonprompt Fraction (Accounting For A Partial Cancellation Between pp And PbPb) And MB Selection Efficiency. This Figure Is Taken From Ref. [1]. 64
- 4.14 The Ratio Of The Production Cross Sections Of Inclusive  $\Lambda_c^+$  To Prompt  $D^0$  Versus  $p_T$  From pp Collisions As Well As 0–100% Centrality PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The PbPb Data Point Is Shifted In The Horizontal Axis For Clarity. The 20 And 31% Normalization Uncertainties In pp And PbPb Collisions, Respectively, Are Not Included In The Boxes Representing The Systematic Uncertainties For Each Data Point. The Open Crosses And Open Stars Represent The Predictions Of PYTHIA8 With The CUETP8M1 Tune And With Color Reconnection [69], Respectively. The Solid And Dashed Lines Are The Calculations For Prompt  $\Lambda_c^+$  Over Prompt  $D^0$  Production Ratio From Ref. [47] and Ref. [72], Respectively. All Predictions Are For pp Collisions. This Figure Is Taken From Ref. [1]. . . . . 65
- 5.1 Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T=3-4$  GeV/ $c$  (Left), 4–5 GeV/ $c$  (Middle) And 5–6 GeV/ $c$  In pp Collisions. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . . 69
- 5.2 Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T=6-8$  GeV/ $c$  (Left), 8–10 GeV/ $c$  (Middle) And 10–12.5 GeV/ $c$  In pp Collisions. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . 69

5.3	Invariant Mass Distribution of $\Lambda_c^+$ Candidates With $p_T= 12.5\text{--}15\text{ GeV}/c$ (Left), $15\text{--}20\text{ GeV}/c$ (Middle) And $20\text{--}30\text{ GeV}/c$ In pp Collisions. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.	70
5.4	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 6\text{--}8\text{ GeV}/c$ (Left), $8\text{--}10\text{ GeV}/c$ (Middle) And $10\text{--}20\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 0–90%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	70
5.5	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 12.5\text{--}15\text{ GeV}/c$ (Left), $15\text{--}20\text{ GeV}/c$ (Middle) And $20\text{--}30\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 0–90%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	71
5.6	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 30\text{--}40\text{ GeV}/c$ (Left) In Centrality Range 0–90%, $10\text{--}12.5\text{ GeV}/c$ (Middle) And $12.5\text{--}15\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 0–10%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	71
5.7	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 15\text{--}20\text{ GeV}/c$ (Left), $20\text{--}30\text{ GeV}/c$ (Middle) And $30\text{--}40\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 0–10%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	72
5.8	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 6\text{--}8\text{ GeV}/c$ (Left), $8\text{--}10\text{ GeV}/c$ (Middle) And $10\text{--}12.5\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 30–50%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	72
5.9	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 12.5\text{--}15\text{ GeV}/c$ (Left), $15\text{--}20\text{ GeV}/c$ (Middle) And $20\text{--}30\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 30–50%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	73
5.10	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 30\text{--}40\text{ GeV}/c$ (Left) In Centrality Range 30–50%, $6\text{--}8\text{ GeV}/c$ (Middle) And $8\text{--}10\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 10–30%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	73
5.11	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 10\text{--}12.5\text{ GeV}/c$ (Left), $12.5\text{--}15\text{ GeV}/c$ (Middle) And $15\text{--}20\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 10–30%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	74
5.12	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 20\text{--}30\text{ GeV}/c$ (Left), $30\text{--}40\text{ GeV}/c$ (Middle) Within The Centrality Range 10–30% And $5\text{--}6\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range 50–90%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.	74

5.13	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 6\text{--}8\text{ GeV}/c$ (Left), $8\text{--}10\text{ GeV}/c$ (Middle) And $10\text{--}12.5\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range $50\text{--}90\%$ . The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	75
5.14	Invariant Mass Distribution Of $\Lambda_c^+$ Candidates With $p_T= 12.5\text{--}15\text{ GeV}/c$ (Left), $15\text{--}20\text{ GeV}/c$ (Middle) And $20\text{--}30\text{ GeV}/c$ In PbPb Collisions Within The Centrality Range $50\text{--}90\%$ . The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component. . . . .	75
5.15	The Top Pannels Of Both Plots Show Prompt + Nonprompt Fit Of The Signal $\Lambda_c^+$ DCA Distribution Measured With The Invariant Mass Fit For $p_T$ Range: $8\text{--}12.5\text{ GeV}/c$ In pp Collisions. The Left Plot Is With The Best MC Resolution Scale Factor In DCA Fit. The Right Plot Is From DCA Significance Fit Without Any Smearing, Which Is Used For Systematic Uncertainty Estimation. The Bottom Pannels Of Both Plots Show The Data/Fit Ratios. . . . .	78
5.16	The Top Pannels Of Both Plots Show Prompt + Nonprompt Fit Of The Signal $\Lambda_c^+$ DCA Distribution Measured With The Invariant Mass Fit For $p_T$ Range $12.5\text{--}15\text{ GeV}/c$ In PbPb Collisions In Centrality Class $0\text{--}90\%$ . The Left Plot Is With Best MC Resolution Scale Factor. The Right Plot Is Used For Systematic Uncertainty Estimation. The Bottom Pannels Of Both Plots Show The Data/Fit Ratios. . . . .	79
5.17	$\chi^2$ Of $\Lambda_c^+$ DCA Fit Vs. MC Resolution Scale Factor For $12.5\text{--}15\text{ GeV}/c$ In Centrality Class $0\text{--}90\%$ In PbPb Collisions. . . . .	80
5.18	Acceptance Times Total Efficiency As A Function Of $p_T$ For The pp And PbPb Analysis For Prompt $\Lambda_c^+$ . The Black Spots Correspond To The Acceptance Times Total Efficiency For pp collisions. The Red Stars, Blue Boxes, Yellow Triangles, Green Triangles And Pink Markers Correspond To $0\text{--}90\%$ , $0\text{--}10\%$ , $10\text{--}30\%$ , $30\text{--}50\%$ and $50\text{--}90\%$ In PbPb Collisions, Respectively. . . . .	81
5.19	The $p_T$ -differential Cross Sections For Prompt $\Lambda_c^+$ Production In pp Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The Bottom Panel Shows Data/Predictions Ratios. . . . .	92
5.20	The $p_T$ -differential Cross Sections For Prompt $\Lambda_c^+$ Production In pp Collisions And The $T_{AA}$ -scaled Yields For Five Centrality Regions Of PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. . . . .	93
5.21	The Nuclear Modification Factor $R_{AA}$ Versus $p_T$ For Prompt $\Lambda_c^+$ Production. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The band At Unity Labeled Global Uncertainty Includes The Uncertainties For The Luminosity Of pp Collisions, Number Of MinimumBias Events In PbPb Collisions, And Tracking Efficiency. . . . .	94

5.22	The Ratio Of The Production Cross Sections Of Prompt $\Lambda_c^+$ To Prompt $D^0$ Versus $p_T$ From pp Collisions, As Well As 0–90% And 0–10% Centrality Classes In PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. # ABSTRACT

Due to the large masses, heavy quarks are produced early and experience the full evolution of the medium. The comparison between the nuclear modification factors of heavy flavor and light hadrons can provide insights into the expected flavor dependence of parton energy loss. The relative coalescence contribution to baryon production is expected to be more significant than that to mesons because of their larger number of constituent quarks. In particular, models involving coalescence of charm and light-flavor quarks predict a large enhancement in the  $\Lambda_c^+/D^0$  production ratio in the heavy ion collisions relative to pp collisions and also predict that this enhancement has a strong  $p_T$  dependence.

This dissertation presents the production of inclusive (prompt)  $\Lambda_c^+$  baryons in proton-proton and lead-lead collisions at 5.02 TeV in 2015 (2017 and 2018) with CMS detector at the CERN LHC [1]. These two analyses show that  $\Lambda_c^+$  baryons production is found to be suppressed in heavy ion collisions. This suppression is consistent with the suppression observed in  $D^0$  meson measurements. The  $\Lambda_c^+/D^0$  production ratios in pp collisions are consistent with a model obtained by adding color reconnection in hadronization to PYTHIA8. Also the  $\Lambda_c^+/D^0$  production ratios in pp collisions are consistent with the model that includes enhanced contribution from the decay of excited charm baryons and the model includes the effect of fragmentation and coalescence [1]. There is a hint of an enhancement in the  $\Lambda_c^+/D^0$  production ratio in PbPb collisions in the  $p_T$  range of 6–12.5 GeV/ $c$  compared to pp collisions. The  $\Lambda_c^+/D^0$  ratios in pp and PbPb collisions for  $p_T > 12.5$  GeV/ $c$  are found to be consistent with each other.

# 1. INTRODUCTION

This chapter presents the theoretical basis and the motivations of the experimental studies in this dissertation.

## 1.1 Elementary Particle

All elementary particles can be categorized into two groups by their spin: fermions (particles with semi-integer spin) and bosons (particles with integer spin). The wave function of a system of identical bosons is symmetric under the exchange of any pair of them, while the wave function of a system of identical fermions is anti-symmetric.

Figure 1.1 shows the elementary particles in the Standard Model [2]. There are six types of quarks, known as flavor: up, down, charm, strange, top and bottom. Every quark has a corresponding type of antiparticle, called as an antiquark. All six types of quarks and leptons are fermions and can be further categorized into three generations. The gluon and the photon is the force carrier of the strong and electromagnetic interaction, respectively. The W and Z bosons are the force carriers of the weak interaction. The Higgs boson, which was discovered at the Large Hadron Collider (LHC) [3], [4], explains how most elementary particles acquire their mass [5].

## 1.2 Quantum Chromodynamics

Quantum Chromodynamics (QCD) [7], [8] is a gauge field theory that describes the strong interaction between quarks and gluons. It is the SU(3) component of the Standard Model [2]. This strong interaction is a short-range interaction, on the order of  $10^{-15}\text{m}$ . In QCD, gluons interact with quarks and other gluons via "color charge". The color charge in strong interaction is like the electric charge in electromagnetic interaction. There are three color charges: red, blue and yellow. QCD has three main properties: color confinement, asymptotic freedom and chiral symmetry breaking.

- Color confinement is the phenomenon that particles are all color neutral, and color charged particles, such as individual quark or gluon cannot be isolated [9].

# Standard Model of Elementary Particles

**Figure 1.1.** Elementary Particles Included In The Standard Model. This Figure Is Taken From Wikipedia [6].

- Asymptotic freedom: When the energy scale of strong interactions increases or the length scale decreases, there is a reduction in the strong interactions between quarks and gluons [8], [10], [11].
- Chiral symmetry breaking. (chirality, discrimination between left and right-handed.)

### 1.2.1 Lattice Quantum Chromodynamics

Many physical processes involve hadrons. Since hadrons are composed of quarks and gluons, the properties of hadrons are governed by QCD. Theoretical calculations of these properties require non-perturbative method, and Lattice QCD is a tool to carry out these calculations. In other words, Lattice QCD reformulates QCD on a lattice of discrete space-time points. Of course, any quantity calculated on the lattice would depend on the lattice spacing. Performing the same calculation multiple times with different, decreasing lattice spacing until the scaling regime is reached, could remove the lattice spacing dependence. The details of how the QCD Lagrangian is put on the lattice could be found in Ref. [2].

## 1.3 Quark Gluon Plasma

For a few millionths of a second, shortly after the Big Bang, the universe was filled with an astonishingly hot, dense soup made of all kinds of particles moving at near light speed. This mixture was dominated by quarks and gluons. Under this extreme temperature, quarks and gluons were bound only weakly, free to move on their own, and this is called a quark gluon plasma (QGP) [12], [13], [14].

Lattice QCD predicts that there is a change in the state of matter (a phase transition) from a hadronic system to a nearly free gas of quarks and gluon (QGP). Figure 1.2 shows the temperature vs baryon chemical potential [15]. The line of first-order transition ends somewhere near the high temperature axis, indicated on the diagram by the label 'critical point'.

There are three major states for the QCD system shown in Fig. 1.2 [15]: hadron gas, the QGP state, and the color superconductor. The quark matter phase can be reached either by

**Figure 1.2.** A Sketch Illustrating The Experimental And Theoretical Exploration Of The QCD Phase Diagram [15].

compressing nuclear matter to high density while at rather low temperatures or increase the vacuum. The high density phase are expected to play a key role in the interior of neutron stars. With the temperature and/or density increasing, the deconfinement of quarks and gluons occurs as a consequence of the asymptotic freedom and results in the formation of QGP.

Phase transitions usually involve a change in the symmetry of the system. In the early universe, the quarks were massless and there were an equal number of quarks and antiquarks. In the universe today, after the transition to normal nuclear matter, there is a small difference in the light quark masses - as well as an even larger difference between the light quark masses and those of the other quarks, even between the light quark and the strange quark. This mass difference is caused by chiral symmetry breaking. At high temperature chiral symmetry is expected to be restored.

### 1.3.1 Parton Energy Loss

The QGP state produced in ultra-relativistic heavy ion collisions can last just for a very short time of a few fm/c, so it cannot be directly observed. Parton energy loss is one important signature of the QGP.

In heavy-ion collisions, when the QGP is produced, the out-going partons can lose a large amount of their energy as they traverse the medium, primarily through gluon radiation [16]–[18] and collisional energy loss [19], [20]. Thus, the spectra of produced hadrons will shift toward lower  $p_T$  region compared to pp collisions and thus show suppression at high  $p_T$ .

The nuclear modification factor ( $R_{AA}$ ) is one variable to quantify the parton energy loss. (the ratio of the yield in heavy ion collisions to that in pp collisions scaled by the number of nucleon-nucleon interactions).  $R_{AA}$  is defined as the followings:

$$R_{AA}(p_T) = \frac{1}{\langle T_{AA} \rangle} \frac{dN_{\text{PbPb}}}{dp_T} \bigg/ \frac{d\sigma_{\text{pp}}}{dp_T}. \quad (1.1)$$

$R_{AA} = 1$  means that the heavy-ion collisions is the same as pp collisions. When  $R_{AA} > 1$ , the production is enhanced. When  $R_{AA} < 1$ , the production is suppressed, which is the general expectation for hadrons with high  $p_T$  as a consequence of the in-medium parton energy

loss.

## 1.4 Heavy Ion Collisions

In order to recreate conditions similar to those of the very early universe, accelerators make head-on collisions between massive ions, such as gold or lead nuclei. The Relativistic Heavy-Ion Collider (RHIC) at BNL [21]–[24] and the Large Hadron Collider (LHC) at CERN [25], [26] produce AuAu and PbPb collisions at energies up to 200 GeV/nucleon and 5500 GeV/nucleon, respectively in the center of mass. In these heavy ion collisions the hundreds of proton and neutrons in two such nuclei smash into one another. This forms a miniscule fireball in which everything ”melts” into a QGP. The primary goal of heavy ion collisions is to study the properties of QGP.

In this chapter, the centrality of heavy ion collisions is described.

### 1.4.1 Centrality Reconstruction And Calibration

The size of the proton may be considered negligible in proton-proton collisions. However, the size of the nuclei cannot be ignored in heavy-ion collisions. In principle, the centrality gives the degree of the overlap of two colliding nuclei. (i.e., the centrality class of 0-30% corresponds to the 30% of collisions with the largest overlap of the two nuclei.). However, the collision geometry cannot be measured directly and only the final-state variables such as momentum and energy can be measured. In the CMS experiment, the events are divided into centrality classes according to the sum of transverse energy ( $E_T$ ) measured in the Hadron Forward Calorimeters (which will be described in 2.2.). The distribution of the sum of HF  $E_T$  for a large sample of minimum bias collisions is measured, and is used to divide the data sample into centrality classes (i.e., the top 10% most energy deposited corresponds to centrality class 0-10%). The distribution measured in PbPb collisions at 2.76 TeV is shown in Figure 1.3 [27]. The centrality of a collision can also be determined by other final-state observable like rapidity loss, but the basic principle is the same.

**Figure 1.3.** Distribution Of The Sum Of HF  $E_T$  For A Large Minimum Bias Event Sample Divided Into Centrality Classes Of PbPb Collisions At 2.76 TeV. Figure Is Taken From Ref. [27].

The geometric quantities of heavy ion collisions, such as number of participating nucleons ( $N_{\text{part}}$ ), number of binary nucleon-nucleon collision ( $N_{\text{coll}}$ ), can be calculated by Monte Carlo Glauber model [28], in which each nucleon position in a nucleus is stochastically determined event-by-event. The geometric quantities are estimated by averaging over multiple events in this model. The position of each nucleon in a nucleus is determined according to the Woods-Saxon or Fermi distribution [28]. The nucleons are assumed to move with a straight trajectory along the beam axis. The details of how impact parameter,  $N_{\text{coll}}$  and  $N_{\text{part}}$  distributions are calculated from the Monte Carlo Glauber model is written in Ref. [28].

### 1.5 Open Heavy Flavor Study In Heavy Ion Collisions

Measurements of heavy-quark production provide unique constraints to help us understand parton energy loss and the degree of thermalization in QGP [12] formed in high energy heavy ion collisions. Because of the large masses, heavy quarks are generated via initial hard scattering in heavy ion collisions and experience the whole evolution of the medium. Thus they are effective probes to study the properties of the medium and in-medium interactions [29]. Besides the in-medium interactions, a detailed study of the hadronization process is critical for the interpretation of experimental data. In addition to the fragmentation process, hadron production can also occur via coalescence, in which partons combine with each other while transversing the QGP medium or at the phase boundary [30], [31], in heavy ion collisions. The probability of coalescence has a strong dependence on the  $p_T$  distribution. This probability is observed reduced at high transverse momentum ( $p_T > 6 \text{ GeV}/c$ ), and thus the hadronization process is expected to be dominated by fragmentation.

A significant enhancement of the baryon-to-meson ratio is observed in heavy ion collisions for hadrons with up, down, or strange quarks [32], [33] in  $p_T$  range 2-6  $\text{GeV}/c$ . This enhancement, and its dependence on centrality can be explained in a scenario with hadronization via coalescence. Furthermore, elliptic flow, the second Fourier component of the azimuthal distribution of emitted particles, is found to roughly scale with the number of constituent quarks in the  $p_T$  range of 2-5  $\text{GeV}/c$  at RHIC [34], an observation which is also consistent with the expectation for coalescence.

A significant contribution of coalescence to the hadronization of charm quarks from the QGP medium is supported by various measurements of charmonium and open charm production at RHIC and LHC energies [35]–[43]. One such observable is the nuclear modification factor, which is introduced in section 1.3. At RHIC, the  $R_{AA}$  for  $J/\psi$  mesons with  $p_T \leq 7$  GeV/ $c$  produced in AuAu collisions decreases significantly from peripheral to central collisions [35]. In contrast, in higher energy PbPb collisions at the LHC, the  $J/\psi$   $R_{AA}$  has a much smaller centrality dependence [36], [37]. The difference between the AuAu and PbPb results can be explained by a larger coalescence probability in PbPb collisions because of the larger number of produced charm and anti-charm quarks at the higher center-of-mass energy. The  $R_{AA}$  of  $D^0$  meson in AuAu collisions, can be qualitatively reproduced by models involving coalescence [38], [39]. At the LHC, the measurements of  $D^0$   $R_{AA}$  and  $D^0$  azimuthal anisotropy [40]–[43] are well explained by models involving coalescence.

Due to the larger number of constituent quarks in baryons, the relative coalescence contribution to baryon production is expected to be more significant than that to mesons. Models involving coalescence of charm and light-flavor quarks predict a large enhancement in the  $\Lambda_c^+/D^0$  production ratio in heavy ion collisions relative to pp collisions and also predict that this enhancement has a strong  $p_T$  dependence [44]–[47]. Comparison of  $\Lambda_c^+$  baryon production in pp and lead-lead (PbPb) collisions can thus provide essential insight into understanding heavy-quark transport in the medium and heavy-quark hadronization via coalescence. All discussions of  $\Lambda_c^+$  and  $D^0$  in this thesis also include their corresponding charge conjugate states.

In this thesis, the analyses on inclusive and prompt  $\Lambda_c^+$   $p_T$ -differential cross section in both pp and PbPb collisions, nuclear modification factor in PbPb collisions, and  $\Lambda_c^+/D^0$  in both pp and PbPb collisions with the CMS detector will be presented [1]. The production of prompt  $\Lambda_c^+$  baryons are found to be suppressed in PbPb collision in centrality class 0–90% and 0–10% [1]. A hint shows that there is an enhancement of the prompt  $\Lambda_c^+/D^0$  production ratio in 6–12.5 GeV/ $c$  in PbPb collisions compared to pp results. The  $\Lambda_c^+/D^0$  production ratio in PbPb collisions is consistent with the result from pp collisions when  $p_T > 12.5$  GeV/ $c$  [1]. Apart from these CMS measurements, similar measurements of  $\Lambda_c^+$  are also performed with ALICE, LHCb detector [48]–[51] in different rapidity ranges and different

center of mass energies. The LHCb  $p_T$ -differential cross section results for the rapidity range  $2.0 < y < 4.5$  were found to be compatible with the next-to-leading order Generalized Mass Variable Flavor Number Scheme [50], [52], while the ALICE and CMS values were larger than predictions, for  $|y| < 0.5$  and  $|y| < 1$  [1], [48]. The ALICE  $\Lambda_c^+/D^0$  production ratio for 6-12 GeV/ $c$  in PbPb collisions was noticed to be much larger than pp and pPb collisions, and this difference is possible to be described via a model involving only coalescence in hadronization [49].

## 1.6 Event Simulation

Event generators are software libraries that generate simulated high energy particles physics events. These event generators are based on some theoretical models or frameworks.

### 1.6.1 PYTHIA8 Event Generator

The PYTHIA program is a general-purpose generator for the generation of events in high energy collisions, i.e., for description of collisions at high energies between electrons, protons, photons and heavy nuclei. It contains theory and models for a number of physics aspect, including hard and soft interactions, parton distributions, initial- and final-state parton showers, multiparton interactions, fragmentation and decay [53]. PYTHIA8 with different tunes are used in all analyses described in this thesis. The detailed information could be found in this comprehensive manual in Ref. [53]. Hadronization is performed via an implementation of the Lund string fragmentation model. As  $q$  and  $\bar{q}$  move apart, the potential energy stored in the string increases, and the string may break by production of a new  $q\bar{q}$ , so that the system splits into two colour-singlet systems  $q\bar{q}'$  and  $q'\bar{q}$ . Further breaks may occur unless the invariant mass of either of these string pieces is not large enough. In the Lund string model, the string break-up process is assumed to proceed until only on-mass-shell hadron remain, each hadron corresponding to a small piece of string with a quark in one end and an antiquark in the other [54].

## 2. THE CMS DETECTOR

The work in this thesis is performed using the data collected by the Compact Muon Solenoid (CMS) detector. The CMS detector is a general-purpose detector at the CERN Large Hadron Collider (LHC), which covers broad physics programs, such as the search for and study of the Higgs boson, the exploration of physics beyond the Standard Model, and also heavy ion physics.

Figure 2.1 shows a schematic representation of the CMS detector with its various subsystems in retracted positions. The CMS detector is build around a 13 m long superconducting solenoid magnet with an inner diameter of 6 m. This takes the form of a cylindrical coil of superconducting cables which can generate a magnetic field of 4 Tesla. The actual magnetic filed strength is 3.8 Tesla during data taking. The innermost part is a silicon-based tacker. Then the next one is a scintillating crystal electromagnetic calorimeter, and then the next one is hadron calorimeter. Outside the magnet are the large muon detectors. This chapter presents certain details of the detector subsystems relevant to the analyses in this thesis. A complete description of the CMS detector can be found in Ref. [55]. The detector coordinate system has the origin centered at the nominal collision point inside the experiment, with the z axis pointing along the counterclockwise beam direction, the x axis pointing radially inward towards the center of the LHC ring, and the y axis pointing vertically upward.

### 2.1 The Inner Tracking System

The CMS inner tracking system is designed to precisely and efficiently reconstruct the trajectories of charged particles and the secondary vertices. At the LHC designed luminosity, there will be on average about 1000 particles from more than 20 overlapping proton-proton interactions traversing the tracker for each bunch crossing. The CMS tracker consists of a pixel detector and a silicon strip tracker. This thesis uses both the data collected before the pixel detector upgrade and after the pixel detector upgrade. Before the pixel detector upgrade (from the end of 2016), the pixel detector is with three barrel layers at radii between 4.4 cm and 10.2 cm. Figure 2.2 is a schematic view of the previous CMS tracker (used for 2015 data taking, and these data are used for inclusive  $\Lambda_c^+$  analysis). This pixel detector

# CMS Detector

**Figure 2.1.** A Schematic Representation Of The CMS Detector With Its Various Subsystems In Retracted Positions (CERN)

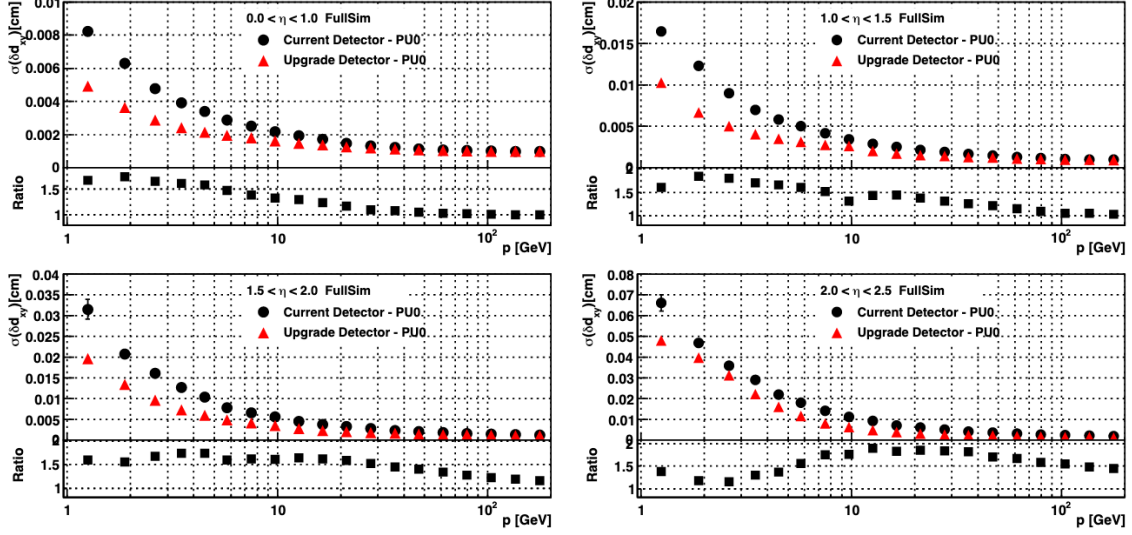

consists of three barrel layers (BPIX) at radii of 4.4 cm, 7.3 cm and 10.2 cm, and two forward/backward disks (FPIX) at longitudinal positions of  $\pm 34.5$  cm and  $\pm 46.5$  cm and extending in radius from about 6 cm to 15 cm. The silicon strip tracker is comprised of 10 barrel layers (TIB and TOB) at midpseudorapidity extending outwards to a radius of 110 cm, and 3 smaller disc layers (TID) and 9 larger disc layers (TEC) at forward pseudorapidity [56].

**Figure 2.2.** Schematic View Of The Previous CMS Tracker (Before The End Of 2016), Showing The Nomenclature Used To Identify Different Sections. Each line Represents A Detector Module. Double Lines Indicate Back-to-back Modules Which Deliver Stereo Hits In The Strip Tracker. This Figure Is Taken From Ref. [57].

After the upgrade, the pixel detector is with four concentric, cylindrical layers with a length of 548.8 mm and radii between 3 cm and 16 cm. The accuracy of the position information can be described by the resolution of track impact parameter. The impact parameter is defined as the minimal distance between the track helix and the primary vertex. Figure 2.3 and 2.4 show respectively the transverse and longitudinal impact parameter resolutions for the upgraded and previous pixel detectors as a function of the track (total) momentum for zero pileup. The ratio of the impact parameter resolutions show that the impact parameter resolution is expected to be greatly improved. This improvement at lower absolute momen-

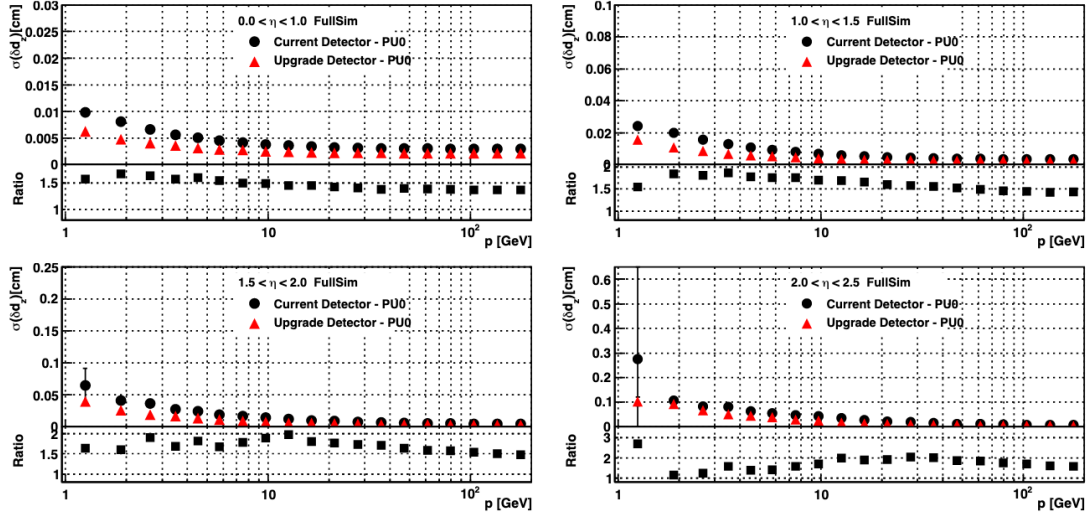

tum is due to the reduction of material in the upgraded detector [57]. Detailed information of the CMS tracking system can be found in Ref. [56], [57].

**Figure 2.3.** Transverse Impact Parameter Resolution For Muon Tracks As A Function Of The Track Momentum For Different  $\eta$  Ranges. The Black Circles Labeled As "Current" Is For The One Before The Upgrade. The Red Triangles Are For The Upgraded Pixel Detector. (Top-left)  $0 < \eta < 1$ ; (Top-right)  $1.0 < \eta < 1.5$ ; (Bottom-left)  $1.5 < \eta < 2$ ; (Bottom-right)  $2 < \eta < 2.5$ . This Figure Is Taken From Ref. [57].

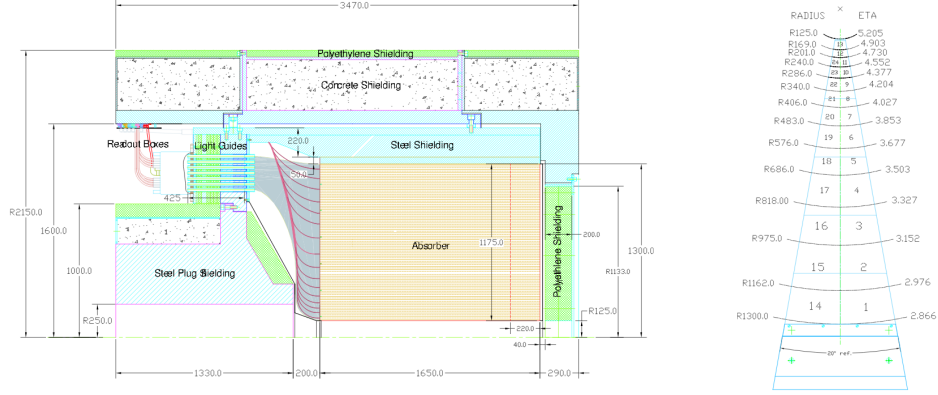

## 2.2 Hadron Forward Calorimeter

The hadron forward calorimeter (HF) is extremely important to heavy ion collisions, since the centrality can be determined with the HF detector, which has been discussed in section 1.4.1. The forward calorimeter is essentially a cylindrical steel structure with an outer radius of 130.0 cm. Azimuthally, each HF calorimeter consists of 18 modular wedges covering  $20^\circ$ . The two HF calorimeters are located 11.2 m away from the interaction region, one on each end, and together they extend the calorimeter coverage from  $|\eta|=3.0$  to 5.2. The steel absorber is composed of 5 mm thick grooved steel and quartz fibers are used as the sensitive material. Each HF calorimeter consists of 432 readout towers, containing long

**Figure 2.4.** Longitudinal Impact Parameter Resolution For Muon Tracks As A Function Of The Track Momentum For Different  $\eta$  Ranges. The Lower Part Of Each Plot Shows The Ratio Of The Previous Detector Resolution To The Upgraded Resolution. (Top-left)  $0 < \eta < 1$ ; (Top-right)  $1.0 < \eta < 1.5$ ; (Bottom-left)  $1.5 < \eta < 2$ ; (Bottom-right)  $2 < \eta < 2.5$ . This Figure Is Taken From Ref. [57].

and short quartz fibers running parallel to the beam, providing information on the shower energy and relative contribution originating from hadrons versus electrons and photons. The cross sectional view and transverse plan of HF calorimeter are shown in Fig. 2.5. A detailed description can be found in Ref [56].

**Figure 2.5.** (Left) The Cross Sectional View Of The HF Calorimeter. (Right) Transverse Segmentation Of A Single 20° Modular Edge Of The HF Detector. Figures Are Taken From Ref. [56].

### 2.3 The Level-1 And High Level Trigger System

For the nominal LHC design luminosity of  $10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , an average of 17 events occurs at the beam crossing frequency of 25 ns. The high input rate must be reduced to accommodate the on-line computer. Therefore, the trigger system is designed to reduce the rate of recording under 1 kHz by keeping the interesting events for analyses and filtering out the uninteresting events. CMS reduces this rate by two steps: (1) The Level-1 (L1) Trigger [58]. (2) High-Level Trigger (HLT) [59]. The L1 triggers are hardware-based system and the HLT triggers are software-based.

The L1 triggers consists of custom-built programmable electronics, which are largely integrated with the readout systems of subdetectors. The L1 triggers are designed to reduce the rate under 100 kHz. Within  $4 \mu\text{s}$ , the system must decide whether to drop an event or pass it to the HLT triggers. The L1 triggers are typically implemented using simple

threshold algorithms written to field-programmable gate arrays (FPGAs), which allow for a fully customizable hardware circuit.

The HLT triggers select events in a similar way, and pass a fraction of these events to the remainder of the online computer resources. For each event, objects such as tracks, muons, and jets can be reconstructed and applied selection criteria to select the interesting events for analyses.

## 2.4 The CMS Computing Model

Unlike previous generations of experiments, the majority of data storage and processing resources are available outside the host laboratory. CMS chooses to use a distributed system of computing resources. Figure 2.6 shows the dataflow between CMS computing centers [56]. The details of the CMS computing system can be found in Ref. [60].

**Figure 2.6.** Dataflow Between Different CMS Computing Centers. This Figure Is Taken From Ref. [56].

Tier-0 is the first tier of the computing system, which is responsible to accept and store the raw data at CERN, perform a real-time reconstruction of the data, and distribute both raw and reconstructed data to Tier-1.

Tier-1 regional centers archives the RAW and reconstructed data (a second copy of RAW and reconstructed RECO data), performs additional reconstruction over the data with the timely calibration, and distribute reconstruction data to Tier-2. Besides these responsibilities, it also provide secure storage and redistribution for Monte Carlo simulated samples which are produced by the Tier-2 and other centers.

The Tier-2 centres have the following responsibilities:

- keep part of the reconstruction data for physics analyses.
- produce Monte Carlo simulations.

### 3. $\Lambda_c^+$ RECONSTRUCTION AND CUT OPTIMIZATION

In this thesis, the  $\Lambda_c^+$  baryons are reconstructed through the hadronic decay channel  $\Lambda_c^+ \rightarrow P^+ K^- \pi^+$  with a branching ratio of  $6.28 \pm 0.32\%$  [2]. Figure 3.1 is the schematic view of the  $\Lambda_c^+ \rightarrow P^+ K^- \pi^+$  decay channel and the variables marked will be defined and discussed below.

**Figure 3.1.** Schematic View Of The  $\Lambda_c^+$  Decay Channel Used In This Thesis.

#### 3.0.1 $\Lambda_c^+$ Reconstruction

$\Lambda_c^+$  candidates are considered by assuming that three tracks having the mass of proton, kaon and pion and then do the permutations. The decay vertex is reconstructed by using a ROOT "KinematicParticleVertexFitter", where least-mean squared minimization is implemented. Several geometric selections are applied in order to reduce the combinatorial background. In particular, the  $\Lambda_c^+$  are selected according to the following topological variables:

- the 2D decay length significance with respect to Beam Spot (BS) for pp collisions and 3D decay length significance with respect to Primary Vertex (PV) for PbPb collisions.

- 2D pointing angle  $\alpha$  with respect to BS for pp collisions and 3D pointing angle  $\alpha$  with respect to PV for PbPb collisions.
- vertex probability.
- track  $p_T$  over  $\Lambda_c^+$   $p_T$  ratio for pp and PbPb collisions.

### 3.0.2 Cut Optimization

The aim of the cut optimization is to maximize the statistical significance (which is  $s/\sqrt{b}$  in this analysis) of the signals with a still reasonable high signal efficiency. The optimal cut minimizing background efficiency for a specific signal efficiency is obtained by the TMVA (Toolit for Multivariate Data Analysis with ROOT) [61]. Rectangular cut and Boosted Decision Tree is chosen as the classification methods in TMVA. The reconstructed  $\Lambda_c^+$  candidates that are matched to the generated  $\Lambda_c^+$  baryons are used as the signal sample and sideband data are used as the background sample. The sideband is defined as the shoulder region right next to the  $\sim 3\sigma$  boundaries of fit to the observed signal on both side (i.e., mass = 2.315–2.355 GeV/ $c^2$  and mass = 2.215–2.255 GeV/ $c^2$ ).

Due to the high luminosity, more than one collision can occur in the same bunch crossing in pp collisions. To make the measurement less sensitive to this pileup effect, two-dimensional variables in the transverse plane with respect to an estimate of the pp interaction region (beamspot) are used in pp collisions.

The cut variables for pp collisions are the followings:

- 2D decay length significance with respect to BS. ("2D dls")
- vertex probability. ("chi2cl")
- 2D pointing angle with respect to BS. ("2D  $\alpha$ ")
- daughter tracks  $p_T$  ratio distribution.

And the cut variables for PbPb collisions are the followings:

- 3D decay length significance with respect to PV. ("3D dls")

- vertex probability.("chi2cl")
- 3D pointing angle with respect to PV.("3D  $\alpha$ ")
- daughter tracks  $p_T$  ratio distribution.

To minimize the size of the analysis tree output, the following initial cuts are applied for the  $\Lambda_c^+$  production with 2015 CMS pp and PbPb data for inclusive  $\Lambda_c^+$  analysis.

- 3D dls with respect to PV  $> 1.0$  and  $> 2.0$  for pp and PbPb collision.
- chi2cl  $> 0.05$  for both pp and PbPb.
- 3D  $\alpha < 0.2$  in PbPb collisions and 3D  $\alpha$  does not have this initial cuts in pp collisions.
- track  $p_T > 1$  GeV/ $c$  and  $> 0.7$  GeV/ $c$  for PbPb and pp.

The initial cuts applied for the  $\Lambda_c^+$  production with 2017/2018 CMS pp and PbPb data for prompt  $\Lambda_c^+$  analysis are:

- 3D dls with respect to PV  $> 2.0$  for PbPb collision only when  $p_T < 30$  GeV/ $c$ .
- chi2cl  $> 0.05$  for both pp and PbPb. (No cuts for PbPb collisions with  $p_T > 30$  GeV/ $c$ .)
- 3D  $\alpha < 0.2$  in PbPb collisions.
- track  $p_T > 1$  GeV/ $c$  and  $> 0.5$  GeV/ $c$  for PbPb and pp collisions, respectively.

The rapidity of the  $\Lambda_c^+$  candidates are required to be within  $\pm 1$ , leading to the daughter track pseudorapidity dominantly reside in  $\pm 1.2$ . Thus,  $|\eta_{track}| < 1.2$  is required in the initial cuts for both analyses. The sample with these initial cuts are used as inputs to the TMVA training.

The optimal cut values are defined as the one that can maximize the significance  $s/\sqrt{b}$ . The statistical significance is defined as this form so that the input signal and background do not need to be normalized to the same number of luminosity. Since the signal background ratio for  $\Lambda_c^+$  is small, if the default statistical significance definition in TMVA package ( $s/\sqrt{s+b}$ ) is used, the optimized cuts are sensitive to the normalized weight.

$s = s \times (\text{signal cut efficiency})$ , where  $s$  is the number of  $\Lambda_c^+$  candidate in data before optimal cuts, and the signal efficiency is  $\Lambda_c^+$  after optimal cuts over the  $\Lambda_c^+$  candidates before optimal cut.

$b = b \times (\text{background cut efficiency})$ , where  $b$  is the amount of background before cuts, and the background efficiency is background after optimal cuts over the background before optimal cut. Signal region is defined as  $|m_{\Lambda_c^+} - m_{\Lambda_c^+ (\text{PDG})}| < 3\sigma$ .  $\sigma$  is the width of  $\Lambda_c^+$  candidates mass fitting in MC.

## 4. PRODUCTION OF INCLUSIVE $\Lambda_c^+$ IN PP AND PbPb COLLISIONS AT 5.02 TeV WITH 2015 CMS DATA

This chapter presents the details of the measurements of inclusive  $\Lambda_c^+$  with 2015 CMS data.

### 4.1 Data Sets And Monte Carlo Simulation

This analysis is performed using the 2015 pp and PbPb data at  $\sqrt{s_{\text{NN}}} = 5.02$  TeV. The luminosity of MB pp, MB PbPb golden json and tracker only json sample are  $38 \text{ nb}^{-1}$ ,  $\sim 21.639 \mu\text{b}^{-1}$  and  $\sim 22.223 \mu\text{b}^{-1}$ , respectively. Thus, the luminosity for MB PbPb data is  $\sim 44 \mu\text{b}^{-1}$ . More data are available from PbPb 30-100% centrality trigger sample which has a luminosity of  $\sim 57.711 \mu\text{b}^{-1}$ . Details of the data sets for inclusive  $\Lambda_c^+$  analysis are summarized in Tab. 4.1. The good quality of the data is ensured by applying the JSON file

**Table 4.1.** CMS 2015 Datasets Used For Inclusive  $\Lambda_c^+$  Production Analysis.

sample	DAS name	Global Tag
pp	/MinimumBias1-20/Run2015E-PromptReco-v1/AOD	auto:run2_data
PbPb	/HIMinimumBias1-11/HIRun2015-PromptReco-v1/AOD	75X_dataRun2_v13

for pp and PbPb respectively. (The file describes which luminosity sections in which runs are considered good and should be processed. In CMS, these files are in the JSON format.)

- Cert\_262081-262328\_5TeV\_PromptReco\_Collisions15\_25ns\_JSON.txt
- Cert\_262548-263757\_PromptReco\_HICollisions15\_JSON\_v2\_PbPb.txt
- Cert\_263685-263757\_PromptReco\_HICollisions15\_TrackerOnly\_JSON.txt

Both pp and PbPb samples were reconstructed using the CMSSW version CMSSW\_7\_5\_8.

#### 4.1.1 Signal Monte Carlo

Monte Carlo simulations of inclusive  $\Lambda_c^+$  productions were made in order to estimate the acceptance  $\times$  reconstruction efficiency ( $\alpha\epsilon$ ) and also to help to evaluate systematic uncertainties. For pp collisions, QCD events are generated by PYTHIA8 [53] with Tune

CUEP8M1 [62] at 5.02 TeV. We use the  $\Lambda_c^+ \rightarrow P^+ K^- \pi^+$  channel, which includes four sub-channels:

- $\Lambda_c^+ \rightarrow P \bar{K}^*(892)^0 \rightarrow P^+ K^- \pi^+$  (1.29%)
- $\Lambda_c^+ \rightarrow \Delta(1232)^{++} K^- \rightarrow P^+ K^- \pi^+$  (1.07%)
- $\Lambda_c^+ \rightarrow \Lambda(1520) \pi^+ \rightarrow P^+ K^- \pi^+$  (0.494%)
- $\Lambda_c^+ \rightarrow P^+ K^- \pi^+$  (nonresonant) (3.4%)

While in Particle Physics Booklet, the decay channel shows like this: The whole branching fraction for  $\Lambda_c^+ \rightarrow P^+ K^- \pi^+$  is  $6.28 \pm 0.32\%$ . The four sub-channels are:

- $\Lambda_c^+ \rightarrow P \bar{K}^*(892)^0$  ( $1.94 \pm 0.27\%$ )
- $\Lambda_c^+ \rightarrow \Delta(1232)^{++} K^-$  ( $1.07 \pm 0.25\%$ )
- $\Lambda_c^+ \rightarrow \Lambda(1520) \pi^+$  ( $2.2 \pm 0.5\%$ )
- $\Lambda_c^+ \rightarrow P^+ K^- \pi^+$  (nonresonant) ( $3.4 \pm 0.4\%$ )

The sum of the branching fractions of the above sub-channels is not equal to that of the whole channel that we use in this analysis. The reason for this is that for the first three sub-channels, there are two decays. We will calculate the branching fraction of  $\Lambda_c^+ \rightarrow P \bar{K}^*(892)^0 \rightarrow P^+ K^- \pi^+$  as an example:  $\Lambda_c^+ \rightarrow P \bar{K}^*(892)^0 \rightarrow P^+ K^- \pi^+$  is from:

- $\Lambda_c^+ \rightarrow P \bar{K}^*(892)^0$  (1.94%)
- $\bar{K}^*(892)^0 \rightarrow K \pi$  ( $\sim 100\%$ )

The second bullet actually is composed of:  $\bar{K}^*(892)^0 \rightarrow K^- \pi^+$  and  $\bar{K}^*(892)^0 \rightarrow \bar{K}^0 \pi^0$ . While the second step is a decay into kaon and pion which are not only  $K^\pm$  and  $\pi^\mp$ . We use Isospin conservation to calculate the branching fraction with the C-G coefficient. We use this pair (I,M) to represent (Isospin, the z-component of Isospin). So we have the followings:

$\pi^0:(1,1)$ ,  $\pi^0:(1,0)$ ,  $K^-:(\frac{1}{2}, \frac{-1}{2})$ ,  $\bar{K}^0:(\frac{1}{2}, \frac{1}{2})$  and  $\bar{K}^*(892)^0:(\frac{1}{2}, \frac{1}{2})$ . From C-G coefficient, we get  $\frac{2}{3}$  for  $\bar{K}^*(892)^0 \rightarrow K^- \pi^+$  and  $\frac{1}{3}$  for the other channel. Then the final branching fraction for  $\Lambda_c^+ \rightarrow P \bar{K}^*(892)^0 \rightarrow P^+ K^- \pi^+$  is  $1.94\% \times \frac{2}{3} = 1.29\%$

The final branching fractions for all the sub-channels are written as the followings:

- $\Lambda_c^+ \rightarrow P \bar{K}^*(892)^0 \rightarrow P^+ K^- \pi^+$  ( $1.94\% \times \frac{2}{3} = 1.29\%$ )
- $\Lambda_c^+ \rightarrow \Delta(1232)^{++} K^- \rightarrow P^+ K^- \pi^+$  (1.07%)
- $\Lambda_c^+ \rightarrow \Lambda(1520) \pi^+ \rightarrow P^+ K^- \pi^+$  ( $2.2\% \times 22.5\% = 0.494\%$ )
- $\Lambda_c^+ \rightarrow P^+ K^- \pi^+$  (nonresonant) (3.4%)

The reason that we calculate this branching fraction is that we need to mix the simulation samples for four sub-channels according to the individual branching fraction to do this analysis, also we need this relative branching fraction to calculate  $\alpha\epsilon$  which will be described in details later.  $\Lambda_c^+$  were forced to decay to these four sub-channels respectively, which means that for these four sub-channels, we should have 4 simulation samples, in each of which,  $\Lambda_c^+$  were forced to decay to the specific sub-channel. Only events with at least one  $\Lambda_c^+$  with  $|y| < 1.2$  and  $|\eta| < 2.4$  were kept. The number of generated output simulation events for  $\Lambda_c^+$  different sub-channels and different  $p_T$  thresholds are shown in Tab. 4.2. A  $\hat{P}_T$  threshold is also used to speed up PYTHIA production of high  $\Lambda_c^+$   $p_T$  events, as also listed in the table. It has been studied that these  $\hat{P}_T$  thresholds are low enough for according  $\Lambda_c^+$   $p_T$ , and will not bias the distribution.

Table 4.2 shows the requested simulation samples for each individual sub-channel. Two  $\hat{P}_T$  bins are used in order to obtain enough sample in different  $p_T$  bins. The  $\hat{P}_T > 0$  GeV/ $c$  condition is used for  $p_T = 5-10$  GeV/ $c$  sample. The  $\hat{P}_T > 4$  GeV/ $c$  condition is used to produce  $p_T > 10$  GeV/ $c$  sample. The  $\hat{P}_T$  cut is selected to ensure 100% efficiency for the signals in the corresponding  $p_T$  bins.

For PbPb productions, selected PYTHIA8 events were embedded into a simulated PbPb background generated by HYDJET (VERSION 1.8, tune "Cymbal5Ev8") [63].

**Table 4.2.**  $\Lambda_c^+$   $p_T$  Threshold, Number Of Output Events And  $\hat{P}_T$  Threshold For Simulation Samples For Inclusive  $\Lambda_c^+$  Analysis In Both pp And PbPb Collisions.

sub-channel	$\Lambda_c^+$ $p_T$ threshold (GeV/c)	# output simulation events	$\hat{P}_T$ (GeV/c)

#### 4.1.2 Event Selection

This analysis uses samples collected from minimum-bias triggers. Event selections are used to reject noise and beam-background event.

For pp, the HLT trigger is HLTL1MinimumBiasHF1OR\_part\*\_v1. To further enhance the statistics for PbPb collisions with centrality 30-100%, the centrality triggers are also used in this inclusive  $\Lambda_c^+$  analysis. The names of the specific centrality triggers are: HLT\_HIL1Centralityext30100MinimumumBiasHF2AND\_part\*\_v1.

The HLT track reconstruction in PbPb collisions corresponds to the standard Heavy ion tracking sequence used in the HI analysis. The HLT track reconstruction in pp includes the first 5 offline tracking iterations. A summary of the track selections applied in the HLT tracking is presented in Table 4.4.

In the offline analysis for PbPb collisions, an additional selection of hadronic collisions is applied by requiring a coincidence of at least three of the HF calorimeter towers, with more than 3 GeV of total energy, from the HF detectors on both sides of the interaction point. Events are required to have at least one reconstructed primary vertex [56]. The primary

vertex is formed by two or more associated tracks and is required to have a distance from the nominal interaction region of less than 15 cm along the beam axis and less than 0.15 cm in the transverse plane. Table 4.3 shows the HLT MB triggers for both pp and PbPb collisions for 2015 CMS data sets used in this inclusive  $\Lambda_c^+$  analysis.

## 4.2 Signal Extraction

In this section, inclusive  $\Lambda_c^+$  candidates and signal yield extraction for pp and PbPb collision are described. Raw yields are extracted in each  $p_T$  interval via unbinned maximum likelihood fit to the invariant mass distribution. The fit function consists of the following components:

- a double Gaussian function with same mean but different width and strength to model the signal shape determined from MC in the each  $p_T$  bin.
- a 3rd-order Chebyshev polynomial function to model the combinatorial background and the swapped  $\Lambda_c^+$  component for both pp and PbPb collisions.

We use the same strategy as Ref. [41]: the signal shape is defined by the simulation, and a floating width parameter is used to accommodate the difference in the signal shape between simulation and data in all  $p_T$  bins except for pp 5–6 GeV/ $c$ . The swapped components are the  $\Lambda_c^+$  signals with incorrect mass assignment from the exchange of the proton and pion mass for lack of particle identification. Although three particles are combined for a  $\Lambda_c^+$  signal, the charge of kaon differs from that of both the proton and the pion, which means that only proton and pion have the possibility for incorrect mass assignment.

In the above signal extraction procedure, we fix the two widths of the double Gaussian and the ratio of the yield between the two Gaussians. We let the mean and also one parameter that corresponds to two widths of the double Gaussian float in this fit in all bins except for pp 5–6 GeV/ $c$ . For pp 5–6 GeV/ $c$ , because there is always a bias in the fit, we scan the value of float width in the range [-0.4,0.4] and perform a toy MC study to find the value of the width with the smallest bias. All parameters, including mean, two sigma of

double Gaussian MC fit are shown in Figure 4.2 and Figure 4.3 (in several  $p_T$  ranges for pp collisions). Figure 4.5–Figure 4.7 show the signal extraction with the default fit function in both pp and PbPb collisions with three centrality ranges. The red line represents the signal on top of the background, while the blue dashed line is the fit function for the background.

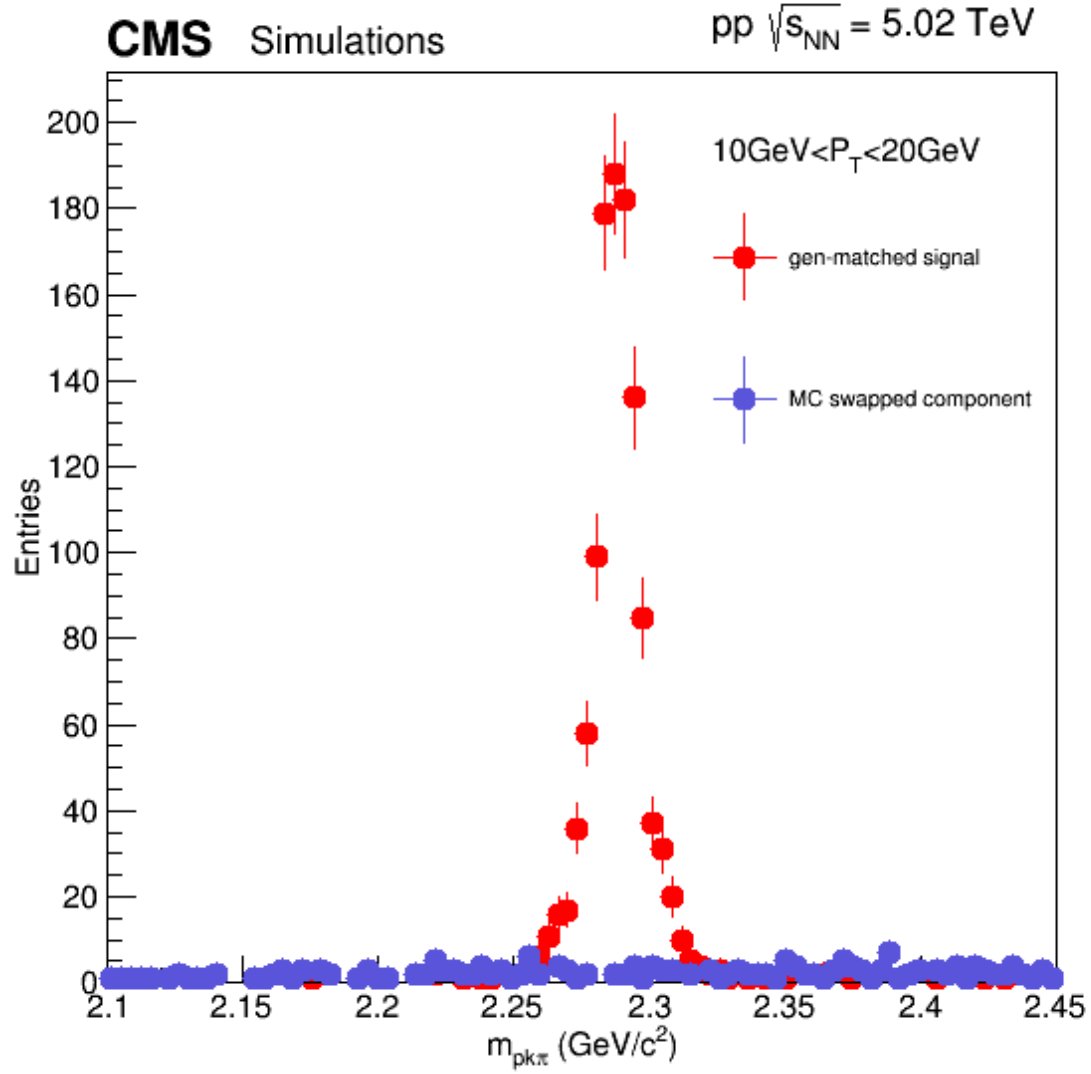

The distribution of swapped component is broad (about 30 times broader) as shown in Figure 4.1 and cannot be distinguished from the combinatorial background. We thus use the Chebyshev polynomial function to represent the combination of the swapped component and the combinatorial background. Figure 4.1 shows the mass distribution of the gen-matched signal as well as the swapped component.

### 4.3 Acceptance And Efficiency Correction

Acceptance and efficiency corrections are applied to the extracted inclusive  $\Lambda_c^+$  yields in order to get the corrected spectra. In this section, we present the acceptance $\times$ efficiency product as a function of  $p_T$  of inclusive  $\Lambda_c^+$ . The studies are performed using PYTHIA8 samples for pp and PYTHIA+HYDJET samples for PbPb collisions.

The correction factor that is relevant for the cross section is the acceptance  $\times$  efficiency. However, to present the effect of acceptance by itself, we also provide the acceptance as a function of  $p_T$ . The acceptance ( $\alpha$ ) is defined as the fraction of  $\Lambda_c^+$  generated in  $|y| < 1$  that have three tracks that fulfill the initial single track acceptance selections (i.e.,  $p_T > 0.7$  GeV/ $c$  (pp) or 1.0 GeV/ $c$  (PbPb) and  $|\eta| < 1.2$ ). Figure 4.8 shows  $\alpha$  as a function of  $\Lambda_c^+$   $p_T$  in pp (upper left) and PbPb collisions in 0–100% (upper right), 0–30% (lower left) and 30–100% (lower right) centrality bins. For all centrality ranges in PbPb collisions, the acceptances are identical as expected. The acceptance in pp is higher than the one in PbPb for  $p_T = 10$ –20 GeV/ $c$  due to looser track  $p_T$  cuts. It is confirmed by assigning the same track  $p_T$  cut where the pp and PbPb acceptance are essentially the same.

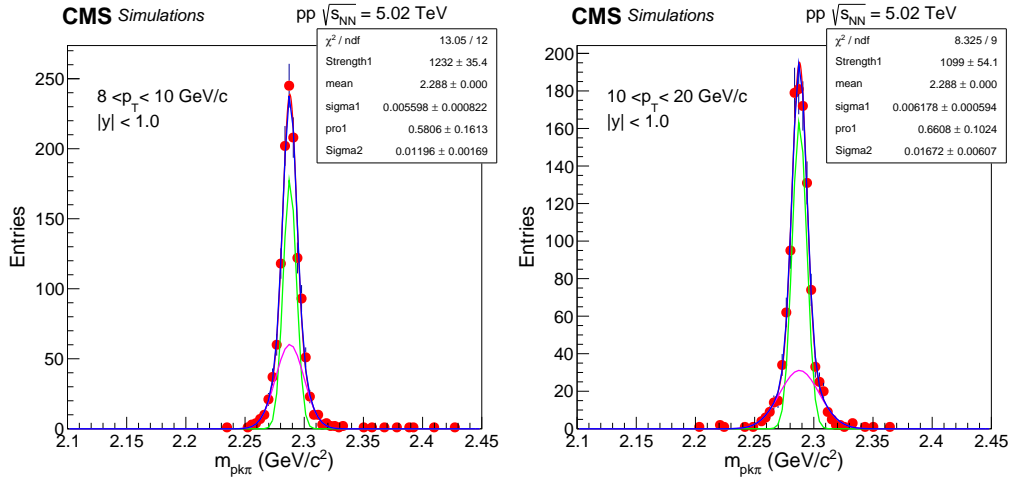

The reconstruction efficiency  $\epsilon_{reco}$  is defined as the fraction of reconstructed  $\Lambda_c^+$  candidates with reconstructed and selected tracks that fulfill the  $\Lambda_c^+$  selection criteria which are the

**Figure 4.1.** The Mass Distribution Of Gen-match Signal And The Swapped Component For pp In  $p_T = 10\text{--}20 \text{ GeV}/c$ . The Red Points Are The Gen-matched Signal And The Blue Points Are Swapped Component.

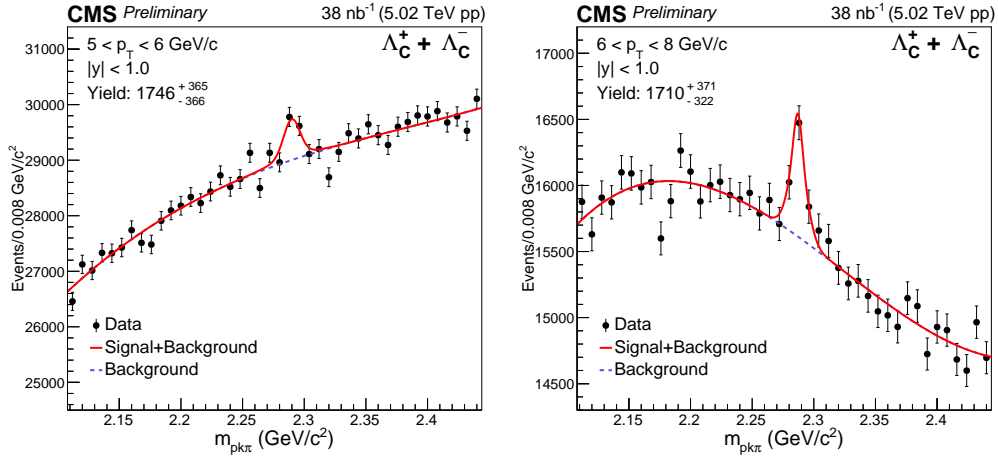

**Figure 4.2.** Double Gaussian Fit For pp Collisions In  $p_T = 5\text{--}6 \text{ GeV}/c$  (Left) And  $6\text{--}8 \text{ GeV}/c$  (Right). In Both Plots, The Blue Line Is The Whole Double Gaussian Fit Function And The Green And Pink Lines Are The Gaussian Fit Function With The Same Mean But Different Widths.

**Figure 4.3.** Double Gaussian Fit For pp Collisions In  $p_T = 8\text{--}10 \text{ GeV}/c$  (Left) And  $10\text{--}20 \text{ GeV}/c$  (Right). In Both Plots, The Blue Line Is The Whole Double Gaussian Fit Function And The Pink Lines Are The Gaussian Fit Function With The Same Mean But Different Widths.

**Figure 4.4.** Double Gaussian Fit For PbPb Collisions In Centrality Range 0–100% (Left), 0–30% (Middle) And 30–100% (Right).

**Figure 4.5.**  $\Lambda_c^+$  Signal Extraction In pp Collisions For  $p_T$  Ranges: 5–6  $\text{GeV}/c$  (Left) And 6–8  $\text{GeV}/c$  (Right). The Red Line Is The Function For The Fore-ground And The Blue Dashed Line Is The Function For The Background.

optimized cuts from TMVA training of each  $p_T$  bins. There are four sub-channels for this channel, so when we calculate the acceptance $\times$ efficiency product, we weight  $A\epsilon_{reco}$  of each sub-channel as:

$$\alpha\epsilon_{reco} = \frac{\sum_{n=1}^4 \alpha_i \epsilon_{reco}(i) \times \mathcal{B}_i}{\sum_{n=1}^4 \mathcal{B}_i}, \quad (4.1)$$

We do the centrality reweight and normalized by  $N_{\text{coll}}$  to account for the following facts:

- 1) there is a difference in centrality distributions between data and MC for PbPb collisions;
- 2) and there is exactly one signal in each simulated event, while more in real data.

**Figure 4.6.**  $\Lambda_c^+$  Signal Extraction In pp Collisions For  $p_T$  Ranges: 8–10 GeV/ $c$  (Left) And 10–20 GeV/ $c$  (Right). The Red Line Is The Function For The Foreground And The Blue Dashed Line Is The Function For The Background.

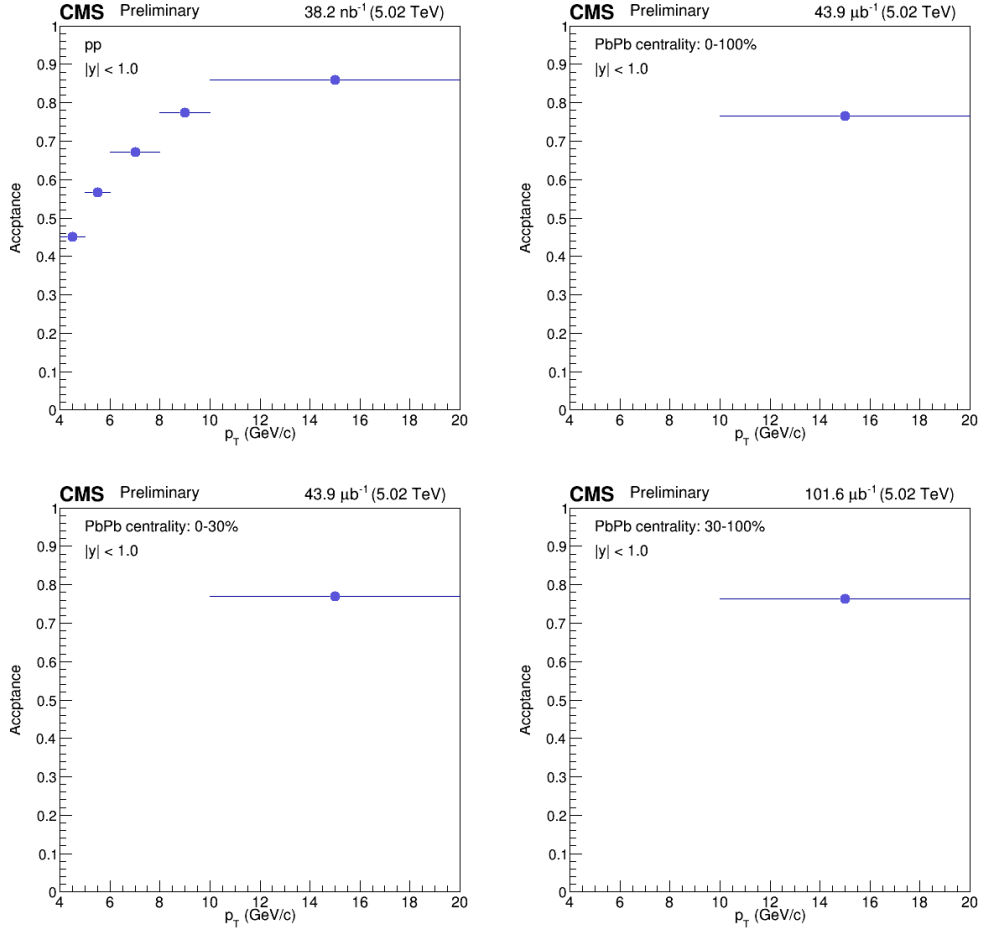

**Figure 4.7.**  $\Lambda_c^+$  Signal Extraction In PbPb Collisions For  $p_T$  Range 10–20 GeV/c In Centrality Class 0–100% (left), 0–30% (Middle) And 30–100% (Right). The Red Line Is The Function For Foreground And The Blue Dashed Line Is The Function For The Background.

When calculating  $\alpha\epsilon_{reco}$ , a  $p_T$  weight is included to avoid the difference between the  $p_T$  shapes from the simulation and real data. The reweight is defined as follows:

$$weight = \frac{\Lambda_c^+ p_T \text{ spectrum}}{\text{gen-level } \Lambda_c^+ p_T \text{ spectrum}} \quad (4.2)$$

For pp, we do the  $p_T$  reweight as discussed above. The  $p_T$  weight is done for several times until the values of  $\alpha\epsilon$  is converged. But for PbPb, we only have one  $p_T$  bin for centrality ranges 0–100%, 0–30% and 30–100%. The  $p_T$  function is obtained via the  $m_T$  scaling from the measurement of  $D^0$  invariant yield in 0–100% centrality [41], [64] since this is the only centrality bin where both  $\Lambda_c^+$  and  $D^0$  have results. Under this scaling assumption, the invariant yields of  $\Lambda_c^+$  and  $D^0$  vs transverse mass  $m_T = \sqrt{p_T^2 + m^2}$  are the same. From  $m^2(\Lambda_c^+) + p_T^2(\Lambda_c^+) = m^2(D^0) + p_T^2(D^0)$ , the invariant yield distribution for  $\Lambda_c^+$  from  $D^0$  can be obtained. Figure 4.9 and Figure 4.10 show the invariant yield of prompt and nonprompt  $\Lambda_c^+$  (normalized by  $T_{AA}$ ) from  $m_T$  scaling. The  $m_T$  scaling is not used in pp collisions, because at low  $p_T$ , there could be significant medium effect according to the model.

There is one additional correction applied to  $\alpha\epsilon_{reco}$  for the PbPb data set. Previous CMS results have found more suppression for prompt than nonprompt  $D^0$  mesons [41], [64], which can be quantified for  $10 < p_T < 20$  GeV/c as  $R_{AA}^{\text{nonprompt}}/R_{AA}^{\text{prompt}} = 1.66 \pm 0.38$ . As nonprompt baryons tend to have greater  $p_T$  and decay farther from the collision point than

**Figure 4.8.** The  $\Lambda_c^+$  Acceptance As A Function Of  $p_T$  In pp Collision As Well As PbPb In 0–30%, 0–100% And 30–100% Centrality Bins.

**Figure 4.9.** Invariant Yield Of Prompt  $\Lambda_c^+$  Derived From  $m_T$  Scaling Of Prompt  $D^0$ .

**Figure 4.10.** Invariant Yield Of Nonprompt  $\Lambda_c^+$  Derived From  $m_T$  Scaling Of Nonprompt  $D^0$ .

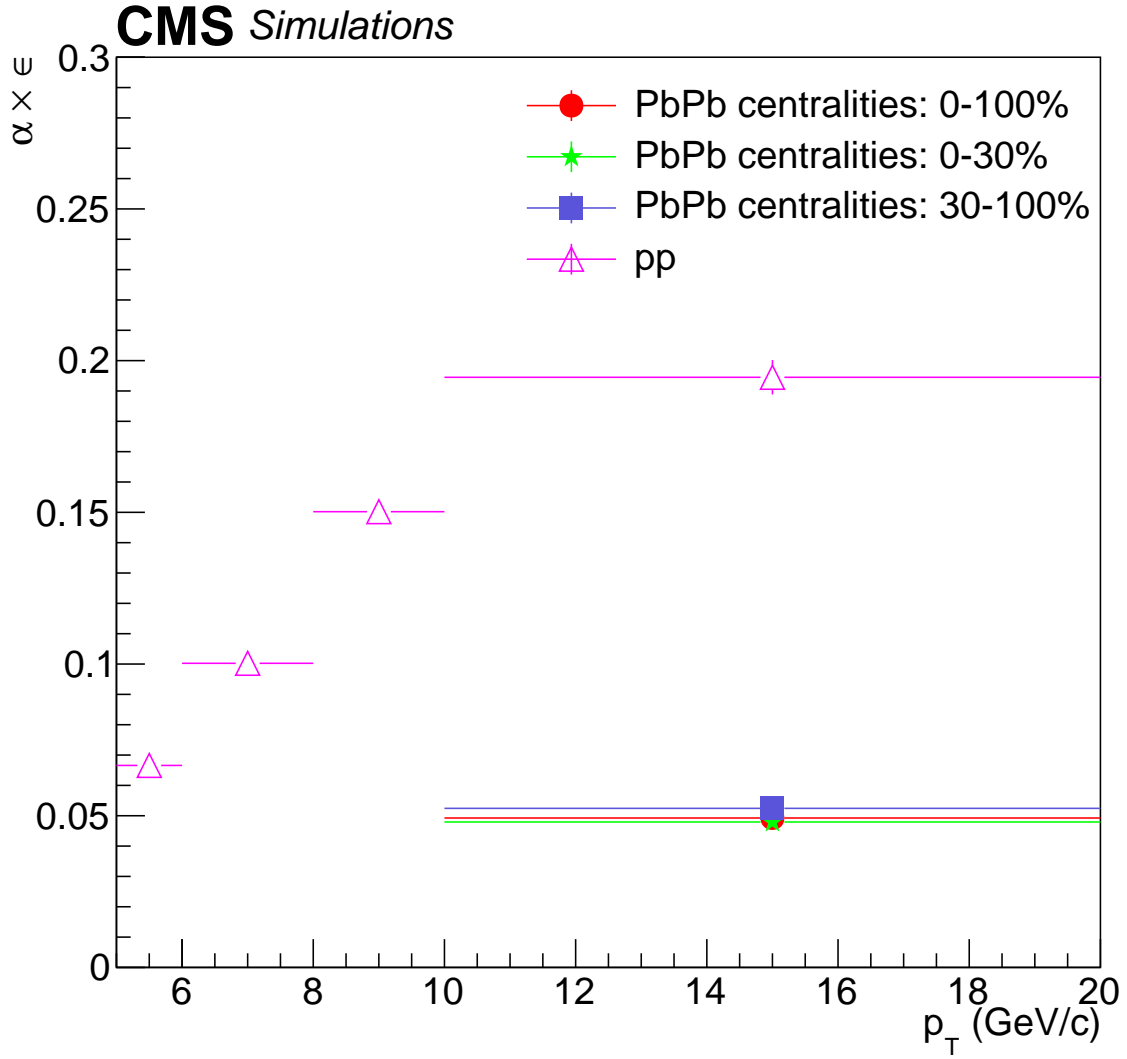

prompt baryons,  $\alpha\epsilon_{reco}$  is larger for nonprompt baryons. Changing the nonprompt fraction to account for the different suppression increases  $\alpha\epsilon_{reco}$  by 15%.

Figure 4.11 shows the acceptance $\times$ efficiency for both pp and PbPb (all centrality bins). Because the optimized cuts for pp are looser than PbPb and the multiplicity for pp is smaller than that of PbPb collisions, the acceptance $\times$ efficiency for pp is higher than PbPb as we expected.

#### 4.4 Systematic Uncertainties

This section presents the studies of systematic uncertainties. Systematic uncertainties arise from the extraction of the raw signal yield, the ability of the MC simulation to reproduce the combined acceptance and efficiency, the branching fraction of the decay mode, and the integrated luminosity [1]. The systematic uncertainty studies are discussed in detail below:

- The systematic uncertainty in the signal yields is obtained by varying the modeling functions that are used for the signal and background contributions.
- The background function is changed from the default third- to second- and fourth-order Chebyshev polynomials. The maximum difference in yield between these two alternative functions and the default fit function is taken as the systematic uncertainty.
- The default signal model function is the sum of two Gaussian functions with parameters chosen as described in Section 4.2. For the pp (PbPb) collision data, the alternative model is a triple (single) Gaussian function with similar procedures used for the parameters.
- As the signal width is fixed for 5–6 GeV/ $c$  in pp collisions, an additional systematic uncertainty is assessed by varying the width by  $\pm 40\%$ , corresponding to the maximum deviations with respect to the simulation observed in other  $p_T$  bins in pp and PbPb collisions.

**Figure 4.11.** The  $\alpha\epsilon$  In PbPb Of Three Centrality Bins And pp Collisions. The Closed Squares, The Closed Stars And The Closed Circles Represent  $\alpha\epsilon$  In PbPb Collisions Of Centrality Range 30–100%, 0–30% And 0–100%, Respectively. The Pink Triangles Represent  $\alpha\epsilon$  Of pp Collisions.

- The uncertainty measures the effect of the selection criteria variation. We define a double ratio as:

$$\mathcal{DR} = \frac{N_{\text{Data}}(\text{varied})}{N_{\text{Data}}(\text{nominal})} \bigg/ \frac{N_{\text{MC}}(\text{varied})}{N_{\text{MC}}(\text{nominal})}, \quad (4.3)$$

where  $N_{\text{Data}}(\text{nominal})$  and  $N_{\text{Data}}(\text{varied})$  are the yields obtained from data using the default and alternative selection criteria, respectively, and  $N_{\text{MC}}(\text{nominal})$  and  $N_{\text{MC}}(\text{varied})$  are the corresponding yields from the simulated events.

For each of the topological selection criteria, the double ratio is evaluated at many different values of the selection criterion. For all but the  $\alpha$  cut in PbPb collisions,  $\mathcal{DR}$  is plotted as a function of the selection value and fit to a linear function. The difference between unity and the value of the fitted line at the point where no selection is applied, is taken as the systematic uncertainty. For the  $\alpha$  requirement in PbPb collisions, the systematic uncertainty is obtained from the biggest differences between unity and the value of  $\mathcal{DR}$  from all of the alternative selection values. Combining the results of the three topological selection criteria systematic uncertainties in quadrature results in final uncertainties due to selection cut for both pp and PbPb collisions [1].

- a potential mismodeling of the  $p_T$  distribution of  $\Lambda_c^+$  baryons because  $\alpha\epsilon$  is strongly dependent on the  $\Lambda_c^+ p_T$ . In pp collisions, the default  $p_T$  shape is derived from the data. For PbPb collisions, the default  $p_T$  shape is obtained from  $m_T$  scaling of the measured  $D^0 p_T$  spectrum. For each data set, two alternative  $p_T$  spectra, one from PYTHIA8 and one from PYTHIA8 with color reconnection (will be described in Section 4.5) are considered and the maximum deviation in  $A\epsilon$  is taken as the systematic uncertainty [1].
- imprecise knowledge of the resonant substructure of the  $pK^- \pi^+$  decay mode [2]. The  $\alpha\epsilon$  is the weighted sum of the four known sub-channels. The branching ratio for each sub-channel has an uncertainty [2]. The systematic uncertainty associated with this is evaluated by determining  $\alpha\epsilon$  for each sub-channel and randomly adjusting the weights by the uncertainties of each branching fraction. The systematic uncertainty is obtained

from the standard deviation of a Gaussian fit to the different average  $\alpha\epsilon$  values for both pp and PbPb events [1].

- the track reconstruction efficiency, which is 4% for pp collisions [41] and 5% for PbPb collisions [65]. As there are three tracks in the  $\Lambda_c^+$  decay, the corresponding uncertainties on the measured  $p_T$  spectra are 12 and 15% for pp and PbPb, respectively, while for the  $\Lambda_c^+/D^0$  production ratio, the uncertainties are 4 and 5%, respectively [1].
- possible mismodeling of the nonprompt component, namely  $\Lambda_c^+$  from hadron decays, in the inclusive  $\Lambda_c^+$  sample. The inclusive  $\alpha\epsilon$  is the weighted sum of prompt and nonprompt  $\alpha\epsilon$  according to the prompt and nonprompt fractions. As found using the standard PYTHIA8 MC sample, the nonprompt  $\alpha\epsilon$  is generally 3-4 times larger than the prompt  $\alpha\epsilon$  and so an incorrect nonprompt fraction in PYTHIA8 will result in an incorrect  $\alpha\epsilon$  for the inclusive sample. To evaluate this systematic uncertainty, an alternative method is used to obtain the final result based on a fixed-order plus next-to-leading logarithm (FONLL) calculation [66]. Since there is no direct predictions for  $\Lambda_c^+$  cross sections in FONLL, a generator-only PYTHIA8 sample of nonprompt  $\Lambda_c^+$  events is reweighted to match the  $p_T$ -differential hadron cross section from a fixed-order plus next-to-leading logarithm (FONLL) calculation [66]. The resulting  $p_T$ -differential cross section for nonprompt  $\Lambda_c^+$  baryons is multiplied by the appropriate luminosity, branching fractions, and  $\alpha\epsilon$  for nonprompt  $\Lambda_c^+$  events to obtain an estimate of the number of reconstructed nonprompt  $\Lambda_c^+$  baryons in each  $p_T$  bin. Subtracting this value from the measured number of reconstructed  $\Lambda_c^+$  baryons gives the number of reconstructed prompt  $\Lambda_c^+$  baryons. These reconstructed prompt yields are then corrected using the prompt  $\alpha\epsilon$  as well as luminosity and branching fractions to estimate the  $p_T$ -differential cross section for prompt  $\Lambda_c^+$  baryons. Finally, the two cross sections give an alternative estimate of the nonprompt fraction in each  $p_T$  bin, and therefore an alternative estimate of the weighted inclusive  $\alpha\epsilon$  value. The systematic uncertainty is taken as the difference between the nominal and alternative  $\alpha\epsilon$  values. Besides the same method which is applied to pp collision for PbPb collisions, an additional systematic

uncertainty is assessed by taking the difference between applying and not applying the correction for different values of  $R_{AA}$  for nonprompt and prompt  $\Lambda_c^+$  baryons [1].

- The overall  $\Lambda_c^+ \rightarrow pK^- \pi^+$  branching fraction uncertainty is 5.3% [2]. The uncertainties in the integrated luminosity in pp collisions and the MB selection efficiency in PbPb collisions are 2.3% [67] and 2.0% [68], respectively. The uncertainties in  $T_{AA}$  are listed in Table 4.5.

For the measurement of the  $p_T$  spectra, the uncertainties associated with the  $\Lambda_c^+ \rightarrow pK^- \pi^+$  branching fraction and subresonant contributions, the luminosity and MB selection efficiency, and the nonprompt fraction contribute only to the overall normalization and are labeled global uncertainties. Adding these contributions in quadrature yields global uncertainties of 21% (31%) for pp (PbPb) collisions. In measuring the nuclear modification factor  $R_{AA}$ , the uncertainties associated with the branching fraction and subresonant contributions cancel and the nonprompt fraction uncertainty partially cancels. In calculating the  $\Lambda_c^+/D^0$  production ratio, the uncertainties associated with  $D^0$  from the yield extraction, selection criteria efficiency, and  $p_T$  shape are obtained from Ref. [41], while the uncertainties in the integrated luminosity in pp collisions and the MB selection efficiency in PbPb collisions cancel [1]. The overview for the relative systematic uncertainties for all the measurements are in Tab. 4.6-4.10.

**Table 4.5.** Summary Of The  $\langle N_{\text{coll}} \rangle$ ,  $\langle T_{AA} \rangle$ , And  $\langle N_{\text{part}} \rangle$  Values For Three PbPb Centrality Ranges At 5.02 TeV.

Centrality	$\langle T_{AA} \rangle [\mu b^{-1}]$	$\langle N_{\text{part}} \rangle$	$\langle N_{\text{coll}} \rangle$
0–30%	$15.41^{+0.33}_{-0.47}$	$270.7^{+3.2}_{-3.4}$	$1079^{+74}_{-78}$
30–100%	$1.41^{+0.09}_{-0.06}$	$46.8^{+2.4}_{-1.2}$	$98^{+8}_{-6}$
0–100%	$5.61^{+0.16}_{-0.19}$	$114.0^{+2.6}_{-2.6}$	$393^{+26}_{-28}$

## 4.5 Results

This section presents the  $p_T$ -differential cross section and  $R_{AA}$  of inclusive  $\Lambda_c^+$  in both pp and PbPb collisions (within three centrality classes), and the  $\Lambda_c^+/D^0$  production ratio in both pp and PbPb collisions (within centrality: 0–100%).

The inclusive  $\Lambda_c^+$   $p_T$ -differential cross section in pp collisions is defined as

$$\left. \frac{d\sigma_{\text{pp}}^{\Lambda_c^+}}{dp_T} \right|_{|y|<1} = \frac{1}{2\mathcal{L}\Delta p_T\mathcal{B}} \frac{N_{\text{pp}}^{\Lambda_c^+}|_{|y|<1}}{\alpha\epsilon}, \quad (4.4)$$

where  $N_{\text{pp}}^{\Lambda_c^+}|_{|y|<1}$  is the  $\Lambda_c^+$  yield extracted in each  $p_T$  bin,  $\mathcal{L}$  is the integrated luminosity,  $\Delta p_T$  is the width of each  $p_T$  bin,  $\mathcal{B}$  is the branching ratio of the decay, and  $\alpha\epsilon$  is the product of the acceptance and efficiency. The factor of  $\frac{1}{2}$  accounts for averaging the particle and antiparticle contributions.

The inclusive  $\Lambda_c^+$  cross section in PbPb collisions is presented as

$$\frac{1}{\langle T_{\text{AA}} \rangle} \left. \frac{dN_{\text{PbPb}}^{\Lambda_c^+}}{dp_T} \right|_{|y|<1} = \frac{1}{\langle T_{\text{AA}} \rangle} \frac{1}{2N_{\text{events}}\Delta p_T\mathcal{B}} \frac{N_{\text{PbPb}}^{\Lambda_c^+}|_{|y|<1}}{\alpha\epsilon}, \quad (4.5)$$

where  $N_{\text{events}}$  is the number of MB events used for the analysis and  $\langle T_{\text{AA}} \rangle$  is the nuclear overlap function, which is the average number of nucleon-nucleon (NN) binary collisions ( $\langle N_{\text{coll}} \rangle$ ) divided by the NN cross section, and can be interpreted as the NN-equivalent integrated luminosity per heavy ion collision.

The values of  $\langle T_{\text{AA}} \rangle$ ,  $\langle N_{\text{coll}} \rangle$ , and the average number of participating nucleons ( $\langle N_{\text{part}} \rangle$ ), generated with a Glauber model [28], are the averages of these quantities over events in the given centrality range, and are listed in Table 4.5.

Figure 4.12 shows the  $p_T$ -differential cross section of inclusive  $\Lambda_c^+$  baryon production in pp collisions for the range of  $5 < p_T < 20$  GeV/ $c$  and the  $T_{\text{AA}}$ -scaled yields in PbPb collisions for the range of  $10 < p_T < 20$  GeV/ $c$ , for three centrality classes. The 21% (31%) normalization uncertainty for the pp (PbPb) results is not included in the boxes representing the systematic uncertainties for each data point. While the shape of the  $p_T$  distribution in pp collisions is consistent with the inclusive production calculation from PYTHIA8 using tune CUETP8M1 and activating the “SoftQCD:nondiffractive” processes, the data are systematically higher. The hadronization in PYTHIA8 can be modified by adding a color reconnection (CR) mechanism in which the final partons in the string fragmentation are considered to be color connected in such a way that the total string length becomes as short as possible [69]. The calculations using the recommended color reconnection model from Ref. [69] are consis-

tent with our  $p_T$ -differential cross section in pp collisions. The  $p_T$ -differential cross section in pp collisions is also compared to the GM-VFNS perturbative QCD calculations [70], which includes only prompt  $\Lambda_c^+$  baryon production. The GM-VFNS prediction is significantly below our data for  $p_T < 10$  GeV/ $c$ , similar to the difference found by ALICE [48]. PYTHIA8 predicts that 8–15% of generated  $\Lambda_c^+$  baryons arise from hadrons, with the low (high) value corresponding to the  $\Lambda_c^+$   $p_T$  interval  $5 < p_T < 6$  GeV/ $c$  ( $10 < p_T < 20$  GeV/ $c$ ). Therefore, accounting for the effects of nonprompt  $\Lambda_c^+$  production will only marginally reduce the disagreement with the GM-VFNS prediction [1].

The nuclear modification factor,  $R_{AA}$  of  $\Lambda_c^+$  is defined as the followings:

$$R_{AA}(p_T) = \frac{1}{\langle T_{AA} \rangle} \frac{dN_{\text{PbPb}}^{\Lambda_c^+}}{dp_T} \bigg/ \frac{d\sigma_{\text{pp}}^{\Lambda_c^+}}{dp_T}. \quad (4.6)$$

The nuclear modification factor  $R_{AA}$  for inclusive  $\Lambda_c^+$  baryons in the  $p_T$  range 10–20 GeV/ $c$  is shown in Fig. 4.13 as a function of the number of participating nucleons  $\langle N_{\text{part}} \rangle$  for PbPb collisions. The results suggest that  $\Lambda_c^+$  is suppressed in PbPb collisions for  $p_T > 10$  GeV/ $c$ , but no conclusion can be drawn because of the large uncertainties. The difference in  $R_{AA}$  values between the 0–30% and 30–100% centrality ranges is consistent with an enhanced suppression in the more central PbPb collisions [1].

Figure 4.14 shows the  $\Lambda_c^+/D^0$  production ratio as a function of  $p_T$  for pp collisions and PbPb collisions in the centrality range 0–100%. The production ratio found from pp collisions is similar in shape versus  $p_T$  but about three times larger in magnitude compared to the calculation from PYTHIA 8.212 tune CUETP8M1. Results using the Monash 2013 [71] tune are found to be consistent with those from the CUETP8M1 tune. Besides providing a reasonable description of  $\Lambda_c^+$  baryon  $p_T$ -differential cross sections, Fig. 4.14 shows that calculations using a color reconnection model are consistent with our results for the  $\Lambda_c^+/D^0$  production ratio in pp collisions [1].

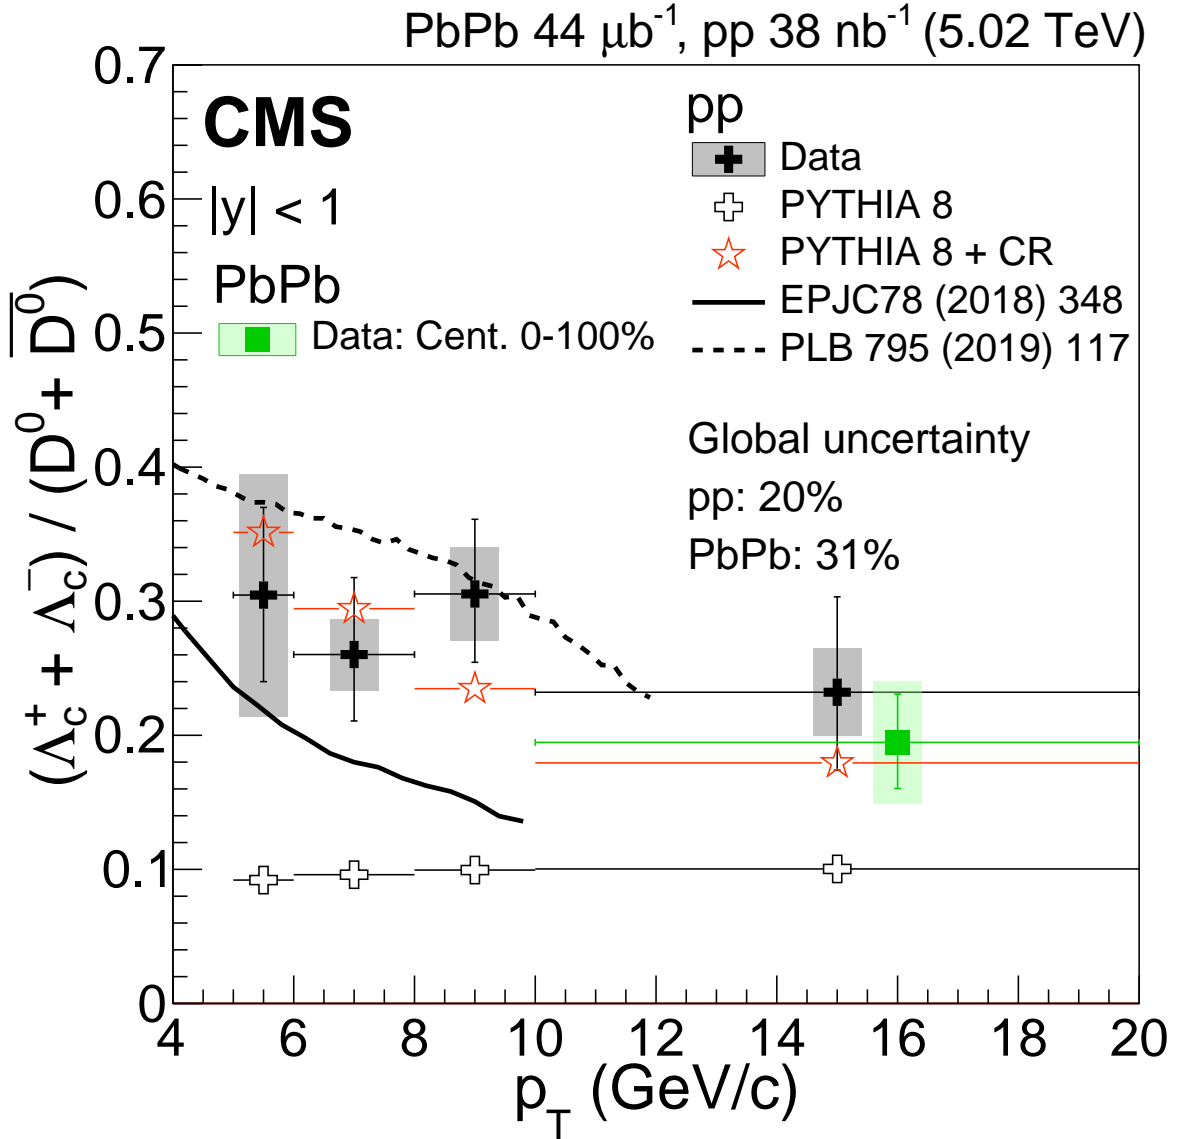

**Figure 4.12.** The  $p_T$ -differential Cross Sections For Inclusive  $\Lambda_c^+$  Production In pp Collisions And The  $T_{AA}$ -scaled Yields For Three Centrality Regions Of PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The PbPb Data Points Are Shifted In The Horizontal Axis For Clarity. Predictions For pp Collisions Are Displayed For PYTHIA8 With The CUETP8M1 Tune (Open Crosses), PYTHIA8 With Color Reconnection [69] (Open Stars), And GM-VFNS [70] (Open Circles Labeled “JHEP 12 (2017) 021”) Along With Ratios To The Data In The Lower Two Panels. The PYTHIA8 (GM-VFNS) Predictions Are For Inclusive (Prompt)  $\Lambda_c^+$  Production. The Error Bars On The GM-VFNS Prediction Account For The Scale Variation Uncertainty. The Lower Panels Show The Data-to-prediction Ratio For pp Collisions With Inner And Outer Error Bars Corresponding To The Statistical And Total Uncertainty In The Data, Respectively, And The Shaded Box At Unity Indicating The 21% Normalization Uncertainty. The Shaded Boxes In The Bottom Panel Represent The GM-VFNS Uncertainty. This Figure Is Taken From Ref. [1].

**Figure 4.13.** The Nuclear Modification Factor  $R_{AA}$  Versus  $\langle N_{\text{part}} \rangle$  For Inclusive  $\Lambda_c^+$  Production. The Error Bars Represent The PbPb Yield Statistical Uncertainties. The Boxes At Each Point Include The PbPb Systematic Uncertainties Associated With The Signal Extraction,  $p_T$  Spectrum, Selection Criteria, Track Reconstruction, And  $T_{AA}$ . The Band At Unity Labeled pp Uncertainty Includes These Same Uncertainties For The pp Data (Except For  $T_{AA}$ ) Plus The Uncertainties In pp Yield And Luminosity. The Band At Unity Labeled PbPb Includes The Uncertainty From The Nonprompt Fraction (Accounting For A Partial Cancellation Between pp And PbPb) And MB Selection Efficiency. This Figure Is Taken From Ref. [1].

**Figure 4.14.** The Ratio Of The Production Cross Sections Of Inclusive  $\Lambda_c^+$  To Prompt  $D^0$  Versus  $p_T$  From pp Collisions As Well As 0–100% Centrality PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The PbPb Data Point Is Shifted In The Horizontal Axis For Clarity. This Figure Is Taken From Ref. [1].

## 5. PRODUCTION OF PROMPT $\Lambda_c^+$ IN PP AND PBPB COLLISIONS AT 5.02 TEV WITH 2017 AND 2018 CMS DATA

This chapter presents the details of the measurements of prompt  $\Lambda_c^+$  with 2017 and 2018 CMS data. Since the luminosity of 2017 pp and 2018 PbPb is 6 and 13 times larger than 2015 CMS data, respectively, lower and higher  $p_T$  ranges could be achieved and the prompt component of  $\Lambda_c^+$  could be distinguished from data.

### 5.1 Data Sets And Monte Carlo Simulation

This analysis is performed using 2017 pp and 2018 PbPb data at  $\sqrt{s_{NN}} = 5.02$  TeV. The luminosity for ZeroBias pp and MinimumBias PbPb is  $252 \text{ nb}^{-1}$  and  $0.58 \text{ nb}^{-1}$ , respectively. Details of the data sets for prompt  $\Lambda_c^+$  analysis are summarized in Table 5.1. The good

**Table 5.1.** CMS 2017 And 2018 Data Sets Used In The Prompt  $\Lambda_c^+$  Production Analysis.

sample	DAS name	Global Tag
pp	/HIZeroBias1-12/Run2017G-17Nov2017-v1/AOD	94X_dataRun2_ ReReco_EOY17_v6

quality of the data is ensured by applying the JSON file for pp and PbPb respectively. (JSON files has been introduced in 4.1.)

- Cert\_306546-306826\_5TeV\_EOY2017ReReco\_Collisions17\_JSON.txt
- Cert\_326381-327564\_HI\_PromptReco\_Collisions18\_JSON.txt

pp and PbPb samples were reconstructed using CMSSW version CMSSW\_9\_4\_10 and CMSSW\_10\_3\_3\_patch1.

### 5.1.1 Event Selection

This analysis uses samples collected from Zero-bias and Minimum-bias triggers. Event selections are used to reject noise and beam-background event.

The following offline event selection criteria are applied to each PbPb event to remove background from the sources such as beam-gas collisions, beam scraping events and electromagnetic interactions (ultra-peripheral collisions):

- `pprimaryVertexFilter`: In the  $B=3.8$  T data, where tracks are reconstructed, requirement of a reconstructed 2-track primary vertex was imposed. In central events, the minimum  $p_T$  requirement was increased, and the tracking region was narrowed down, to keep the maximum number of fitted tracks stable around 40–60, ensuring time-efficient reconstruction. When tracks are not reconstructed, i.e.  $B=0$  T, the z-vertex position is obtained by maximizing the compatibility of pixel cluster length and global z-positions with a vertex hypothesis. The vertex is only accepted if it lies between  $\pm 25$  cm from the center of the detector. The requirement of an accepted vertex removes non-inelastic collision events (e.g. beam-gas UPC) with large HF energy deposits but very few pixel hits.
- `phfCoincFilter2Th4`: This filter requires at least 2 towers on each side of the interaction point in the HF with tower above 4 GeV threshold. The requirement removes approximately 99% of UPC events.
- `pclusterCompatibilityFilter`: A particle traversing a pixel module at some angle leaves a cluster with a width proportional to its angle of incidence. The expected width of the cluster can be determined by the particle pseudorapidity and z-position of the collision vertex. For a given z-position, one can determine the number of clusters in an event that have a width compatible with the hypothesis that the collision vertex was at the z-position. One can scan the z-axis to determine how many clusters are compatible with a vertex at each position. This technique can be used to locate the z-position of a collision vertex, or determine if a collision likely occurred outside the interaction region (i.e. beam scraping).

- $-15 < PVz < 15$ : The primary vertex is required to be between  $\pm 15$  cm from the center of the detector in the z-direction.

## 5.2 Signal Extraction

In this section,  $\Lambda_c^+$  candidates and signal yield extraction for pp and PbPb collision are described. Raw yield are extracted in each  $p_T$  interval via unbinned maximum likelihood fit to the invariant mass distribution. The fit function consists of the following components:

- a double Gaussian function with same mean but different widths and strengths to model the signal shape determined from MC in the each  $p_T$  bin for pp collisions; a triple Gaussian function with same mean but different widths and strengths to model the signal shape determined from MC in the each  $p_T$  bin for PbPb collisions.
- a Chebyshev polynomial function to model the combinatorial background and the swapped  $\Lambda_c^+$  component for both pp and PbPb collisions. Previous CMS inclusive  $\Lambda_c^+$  analysis [1] already shows that the distribution of swapped component is broad (about 30 times broader) and the shape is very closed to the combinatorial background. The detailed information is in 4.2. The order of the Chebyshev polynomial function is decided by LLR test. The default background fit function for PbPb collisions is Chebyshev pol3 function. The default background fit function for pp collisions is Chebyshev pol1, Chebyshev pol2 and Chebyshev pol3 for 3–5 GeV/c, 5–8 GeV/c, and 8–30 GeV/c.

We use the same strategy as that in the inclusive  $\Lambda_c^+$  analysis [1] (which is described in 4.2): The signal shape is defined by the MC, and the float width parameter is to accommodate the difference of the signal shape between MC and data in all  $p_T$  bins.

## 5.3 Prompt $\Lambda_c^+$ Extraction by DCA Fit

The prompt and nonprompt  $\Lambda_c^+$  are distinguished by fitting the data mix  $\Lambda_c^+$  DCA distribution by a mixture of prompt and nonprompt  $\Lambda_c^+$  DCA from MC samples. The  $\Lambda_c^+$  DCA distributions for prompt and nonprompt  $\Lambda_c^+$  from the MC are expected to be different. The prompt part should have a narrower distribution near 0 while the nonprompt

**Figure 5.1.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T=3-4$  GeV/c (Left),  $4-5$  GeV/c (Middle) And  $5-6$  GeV/c In pp Collisions. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

**Figure 5.2.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T=6-8$  GeV/c (Left),  $8-10$  GeV/c (Middle) And  $10-12.5$  GeV/c In pp Collisions. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

distribution is much wider. There could be a MC-data difference which could influence the prompt and nonprompt  $\Lambda_c^+$  yields obtained by the  $\Lambda_c^+$  DCA fit. To estimate this effect, the resolution from MC is scaled by an arbitrary number, and see which scale will lead to the best 2 component  $\Lambda_c^+$  DCA fit (details below).

The best MC resolution effect scale to match the data is determined by a fit shown in Fig. 5.17. The best scale is at the minimum of  $\chi^2$  vs. scale. The statistic error of the fitted prompt ratio is assigned as the statistic error and the systematic error is assigned as

**Figure 5.3.** Invariant Mass Distribution of  $\Lambda_c^+$  Candidates With  $p_T = 12.5$ – $15$  GeV/ $c$  (Left),  $15$ – $20$  GeV/ $c$  (Middle) And  $20$ – $30$  GeV/ $c$  In pp Collisions. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

**Figure 5.4.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T = 6$ – $8$  GeV/ $c$  (Left),  $8$ – $10$  GeV/ $c$  (Middle) And  $10$ – $20$  GeV/ $c$  In PbPb Collisions Within The Centrality Range 0–90%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

the difference in prompt ratio between the minimal  $\chi^2$  and minimal  $\chi^2 + 2.3$  [2] or the best smearing DCA fit and DCA significance fit without any smearing .

The statistic of  $p_T > 15$  GeV/ $c$  is quite low, and the signal shape is not obvious. The value of number of signal minus the statistical error hits a negative value, which leads to unreasonable fitted prompt ratio. Also, it is not able to extract the signal number for  $3 < p_T < 4$  GeV/ $c$ . The PYTHIA prompt ratio shows that the prompt ratio for  $p_T > 15$  GeV/ $c$  is closed to that of its neighbour bin ( $12.5 < p_T < 15$  GeV/ $c$ ), and also same case for

**Figure 5.5.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T = 12.5\text{--}15 \text{ GeV}/c$  (Left),  $15\text{--}20 \text{ GeV}/c$  (Middle) And  $20\text{--}30 \text{ GeV}/c$  In PbPb Collisions Within The Centrality Range 0–90%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

**Figure 5.6.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T = 30\text{--}40 \text{ GeV}/c$  (Left) In Centrality Range 0–90%,  $10\text{--}12.5 \text{ GeV}/c$  (Middle) And  $12.5\text{--}15 \text{ GeV}/c$  In PbPb Collisions Within The Centrality Range 0–10%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

$3 < p_T < 4 \text{ GeV}/c$ . Thus, the prompt ratio for  $15\text{--}30 \text{ GeV}/c$  is quoted as that for  $12.5\text{--}15 \text{ GeV}/c$ , and the prompt ratio for  $3\text{--}4 \text{ GeV}/c$  is quoted as that for  $4\text{--}5 \text{ GeV}/c$ . The systematic uncertainty due to prompt ratio for these three  $p_T$  bins ( $3\text{--}4$ ,  $15\text{--}20$ , and  $20\text{--}30 \text{ GeV}/c$ ) will be assigned as the biggest difference between the quoted prompt ratio and that predicted by PYTHIA or next-to-leading logarithm (FONLL). There is no FONLL nonprompt  $\Lambda_c^+$  cross section predictions, thus, a generator-only PYTHIA8 sample of nonprompt  $\Lambda_c^+$  events

**Figure 5.7.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T = 15$ –20 GeV/c (Left), 20–30 GeV/c (Middle) And 30–40 GeV/c In PbPb Collisions Within The Centrality Range 0–10%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

**Figure 5.8.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T = 6$ –8 GeV/c (Left), 8–10 GeV/c (Middle) And 10–12.5 GeV/c In PbPb Collisions Within The Centrality Range 30–50%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

is reweighted to match the  $p_T$ -differential b hadron cross section from FONLL calculation. The resulting  $p_T$ -differential cross section for nonprompt  $\Lambda_c^+$  baryons is multiplied by the appropriate luminosity, branching fractions, and  $\alpha\epsilon$  for nonprompt  $\Lambda_c^+$  events to obtain an estimate of the nonprompt ratio of  $\Lambda_c^+$ . All the detailed information is listed in Table 5.2.

The  $s/b$  is so small for  $p_T = 6$ –8 GeV/c, and 10–12.5 GeV/c in centrality class 0–90% and 0–10% in PbPb collisions that these two  $p_T$  bins could not do DCA fit. The prompt ratios

The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

where, P represents prompt  $\Lambda_c^+$  and NP represents nonprompt  $\Lambda_c^+$ . Previous CMS results have found more suppression for prompt than nonprompt  $D^0$  mesons [41], [64], which can be quantified for 6–8 GeV/c (0–100% centrality) as  $\frac{R_{AA}(P)_{D^0}}{R_{AA}(NP)_{D^0}} = 0.675 \pm 0.219$ . This ratio for 10–12.5 GeV/c (0–10% centrality) can be quantified as  $0.83 \pm 0.10$ . The  $\Lambda_c^+/D^0$  in both pp and PbPb is estimated from ALICE results [48], [49].

**Figure 5.13.** Invariant Mass Distribution Of  $\Lambda_c^+$  Candidates With  $p_T = 6\text{--}8$  GeV/c (Left),  $8\text{--}10$  GeV/c (Middle) And  $10\text{--}12.5$  GeV/c In PbPb Collisions Within The Centrality Range 50–90%. The Solid Line Represents The Full Fit And The Dashed Line Represents The Background Component.

The uncertainty due to prompt ratio for these two  $p_T$  bins will be assigned as the quadratic sum of the uncertainty from  $R_{AA}$  ratio and pp prompt ratio. Thus the uncertainty due to prompt ratio is 34.9% for  $6\text{--}8$  GeV/c in centrality range 0–90%, and 24.5% for  $10\text{--}12.5$  GeV/c in centrality range 0–10%. The detailed information of the prompt ratio in PbPb collisions within five centrality classes are shown in Tab. 5.3 and 5.4.

**Table 5.2.** This Table Shows All The Fitted Prompt Ratio Got From The Best MC Resolution Scale Factor, The Systematic Uncertainty Due To DCA Fit And Also The Predicted Prompt Ratio From PYTHIA8 And FNOLL In pp Collisions For  $p_T$  Bins 3–4 GeV/ $c$ , 15–20 GeV/ $c$  And 20–30 GeV/ $c$ .

$p_T$ intervals (GeV/ $c$ )	fitted prompt ratio	PYTHIA	FNOLL	uncertainty (%)
3–4	0.85	0.67	0.98	21.2

**Figure 5.15.** The Top Pannels Of Both Plots Show Prompt + Nonprompt Fit Of The Signal  $\Lambda_c^+$  DCA Distribution Measured With The Invariant Mass Fit For  $p_T$  Range: 8–12.5 GeV/c In pp Collisions. The Left Plot Is With The Best MC Resolution Scale Factor In DCA Fit. The Right Plot Is From DCA Significance Fit Without Any Smearing, Which Is Used For Systematic Uncertainty Estimation. The Bottom Pannels Of Both Plots Show The Data/Fit Ratios.

#### 5.4 Acceptance And Efficiency Correction

Acceptance and efficiency corrections are applied to the extracted  $\Lambda_c^+$  yield in order to get the corrected spectra. In this section, the acceptance $\times$ efficiency as a function of transverse momentum  $p_T$  of  $\Lambda_c^+$  is presented. The studies are performed with PYTHIA8 sample for pp and PYTHIA+HYDJET sample for PbPb.

The same strategy as that in 4.3 has been applied. Besides the  $p_T$  and centrality reweight, the PVz weight is also added to avoid the difference in PVz shape between MC and data. All weights are done for several times until the values of  $\alpha\epsilon$  is converged. Figure 5.18 shows the

**Figure 5.16.** The Top Pannels Of Both Plots Show Prompt + Nonprompt Fit Of The Signal  $\Lambda_c^+$  DCA Distribution Measured With The Invariant Mass Fit For  $p_T$  Range 12.5–15 GeV/ $c$  In PbPb Collisions In Centrality Class 0–90%. The Left Plot Is With Best MC Resolution Scale Factor. The Right Plot Is Used For Systematic Uncertainty Estimation. The Bottom Pannels Of Both Plots Show The Data/Fit Ratios.

acceptance times total efficiency as a function of  $p_T$  for both pp and PbPb collisions within five centrality classes.

## 5.5 Systematic Uncertainties

Systematic uncertainties arise from the extraction of the raw signal yield, the ability of the MC simulation to reproduce the combined acceptance and efficiency, the prompt ratio from DCA fit, the branching fraction of the decay mode, and the integrated luminosity. The detailed systematic uncertainties are described in detail as follows:

The systematic uncertainty in the signal yields is obtained by varying the modeling functions that are used for the signal and background contributions and also the fit range.

**Figure 5.17.**  $\chi^2$  Of  $\Lambda_c^+$  DCA Fit Vs. MC Resolution Scale Factor For 12.5–15 GeV/c In Centrality Class 0–90% In PbPb Collisions.

The background function is changed from the default order to default order +1 Chebyshev polynomials, with the difference in yields between alternative function and default fit function taken as the systematic uncertainty on background fit function. When the effect of changing the background fit function is considered, the signal shape is fixed according to the default fit function to avoid the signal shape changing effect. The systematic uncertainty for the signal PDF has been estimated by changing from the default signal fit function to an alternative signal fit function, for both pp and PbPb collisions. The alternative signal fit function is triple Gaussians, and double Gaussians for pp and PbPb collisions, respectively. The difference in signal yields between alternative signal fit function and the default one is taken as the systematic uncertainty on signal fit function. The systematic uncertainty for the fit range has been estimated by changing the fit range from the default range to alternative fit ranges, for both pp and PbPb collisions. The biggest difference in the signal yields between nominal and alternative fit range is taken as the systematic uncertainty on the fit range.

**Figure 5.18.** Acceptance Times Total Efficiency As A Function Of  $p_T$  For The pp And PbPb Analysis For Prompt  $\Lambda_c^+$ . The Black Spots Correspond To The Acceptance Times Total Efficiency For pp collisions. The Red Stars, Blue Boxes, Yellow Triangles, Green Triangles And Pink Markers Correspond To 0–90%, 0–10%, 10–30%, 30–50% and 50–90% In PbPb Collisions, Respectively.

Five sources of systematic uncertainties associated with the MC modeling of the data are evaluated. The first uncertainty measures the effect of the selection criteria variation, the same method is applied as in section 4.4. For each selection criteria (BDTG value or topological selection criteria), the double ratio is evaluated at many different values of the selection criterion. 6–10 GeV/ $c$  in PbPb collisions in 0–90% centrality class could not do the double ratio scan due to the small  $s/\sqrt{b}$ , the uncertainties for these two  $p_T$  bins are achieved by adding the systematic uncertainty for decay length significance and vertex probability in 10–12.5 GeV/ $c$  (0–90% centrality) and that of pointing angle  $\alpha$  in 8–10 GeV/ $c$  in quadrature.

The second uncertainty arises from a potential mismodeling of the  $p_T$  distribution of  $\Lambda_c^+$  baryons because  $\alpha\epsilon$  is strongly dependent on the  $\Lambda_c^+$   $p_T$ . For both pp and PbPb collisions, the default  $p_T$  shape is derived from the data and the alternative  $p_T$  spectra is from PYTHIA8

with color reconnection (described in section 4.5). The deviation in  $\alpha\epsilon$  is taken as the systematic uncertainty.

The third uncertainty arises from imprecise knowledge of the resonant substructure of the  $pK^- \pi^+$  decay mode [2]. The procedure is described in section 4.4.

The fourth uncertainty associated with the MC modeling of the data is the track reconstruction efficiency, which is the same as that in section 4.4.

The fifth uncertainty arises from the prompt ratio that is got from DCA fit. This is explained in section 5.3.

The overall  $\Lambda_c^+ \rightarrow pK^- \pi^+$  branching fraction uncertainty is 5.3% [2]. The uncertainties in the integrated luminosity in pp collisions and the MB selection efficiency in PbPb collisions are 1.9% [73] and 1.5% [68], respectively.

For the measurement of the  $p_T$  spectra, the uncertainties associated with the  $\Lambda_c^+ \rightarrow pK^- \pi^+$  branching fraction, tracking efficiency, the luminosity and MB selection efficiency are labeled as global uncertainties. Adding these contributions in quadrature yields global uncertainty of 6.8 and 7.4% for pp and PbPb collisions, respectively. In measuring the nuclear modification factor  $R_{AA}$ , the uncertainties associated with the branching fraction and sub-resonant contributions cancel and the prompt fraction uncertainty (for 6–8 GeV/ $c$  in 0–90% centrality class and 10–12.5 GeV/ $c$  in 0–10% centrality class) partially cancels. In calculating the  $\Lambda_c^+/D^0$  production ratio, the uncertainties associated with  $D^0$  from the yield extraction, selection criteria efficiency, and  $p_T$  shape are obtained from Ref. [41], while the uncertainties in the integrated luminosity in pp collisions and the MB selection efficiency in PbPb collisions cancel. Table 5.5–5.18 are the summary tables for relative systematic uncertainties for each measurements for prompt  $\Lambda_c^+$ .

## 5.6 Results

This section presents the  $p_T$  spectrum in both pp and PbPb (5 centrality ranges),  $R_{AA}$ , the  $\Lambda_c^+/D^0$  production ratio in both pp and PbPb collisions.

The  $p_T$ -differential cross section for prompt  $\Lambda_c^+$  in pp collisions is defined as:

$$\left. \frac{d\sigma_{\text{pp}}^{\Lambda_c^+}}{dp_T} \right|_{|y|<1} = \frac{f_{\text{prompt}}}{2\mathcal{L}\Delta p_T\mathcal{B}} \frac{N_{\text{pp}}^{\Lambda_c^+}|_{|y|<1}}{\alpha\epsilon}, \quad (5.2)$$

where  $N_{\text{pp}}^{\Lambda_c^+}|_{|y|<1}$  are the  $\Lambda_c^+$  yields extracted in each  $p_T$  interval,  $\mathcal{L}$  (252/nb for Zero Bias) is the luminosity,  $\Delta p_T$  is the width of the  $p_T$  interval,  $f_{\text{prompt}}$  is the prompt ratio of  $\Lambda_c^+$ ,  $\mathcal{B}$  is the branching ratio of the decay channel that is used in this analysis,  $\alpha\epsilon$  represents the acceptance  $\times$  efficiency correction. The factor 1/2 accounts for the fact that the yield were measured for particles and antiparticles, but the cross section is given for particles only.

The cross section for prompt  $\Lambda_c^+$  PbPb are presented as the followings:

$$\left. \frac{1}{\langle T_{\text{AA}} \rangle} \frac{dN_{\text{PbPb}}^{\Lambda_c^+}}{dp_T} \right|_{|y|<1} = \frac{f_{\text{prompt}}}{\langle T_{\text{AA}} \rangle} \frac{1}{2N_{\text{events}}\Delta p_T\mathcal{B}} \frac{N_{\text{PbPb}}^{\Lambda_c^+}|_{|y|<1}}{\alpha\epsilon}, \quad (5.3)$$

where  $N_{\text{events}}$  are the number of MB events (centrality class 0–90% has 3,395,373,402 events corrected by the event filter),  $\langle T_{\text{AA}} \rangle = \langle N_{\text{coll}} \rangle / \sigma_{\text{pp-inelastic}}$  is the nuclear overlap function, which is equal to the value of  $N_{\text{coll}}$  divided by the pp cross section. Other parameters are the same as those in pp collisions.

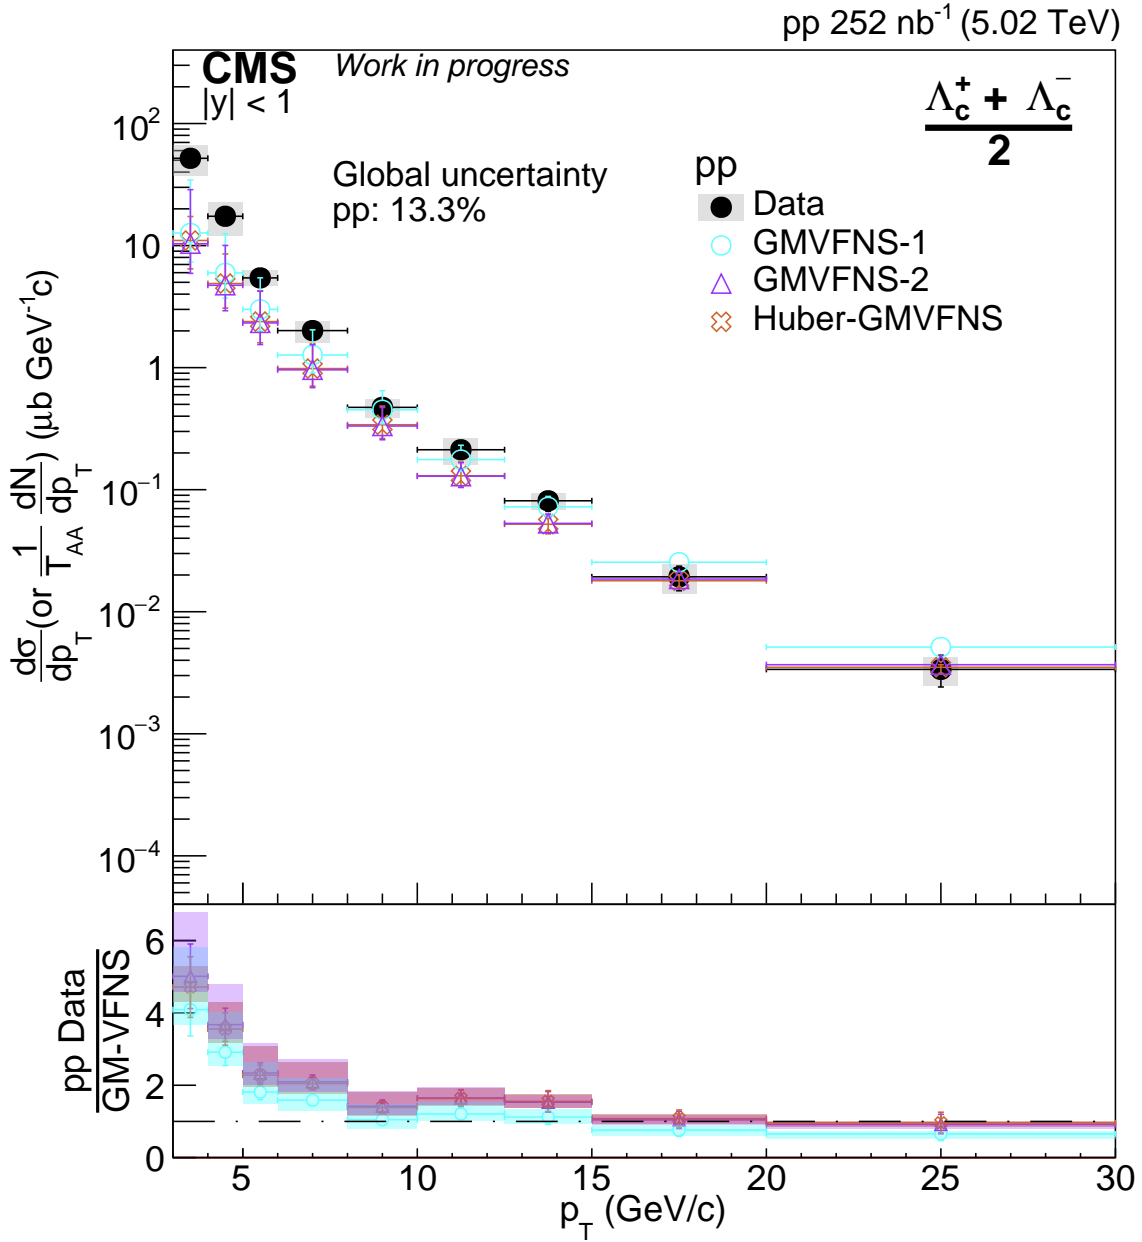

Figure 5.19 and 5.20 show the  $p_T$ -differential cross section of prompt  $\Lambda_c^+$  baryon production in pp collisions for the range of  $3 < p_T < 30$  GeV/ $c$  and the  $T_{\text{AA}}$ -scaled yields in PbPb collisions in five centrality classes. The 13.3% (16.0%) normalization uncertainty for the pp (PbPb) results is not included in the boxes representing the systematic uncertainties for each data point.

$R_{\text{AA}}$  of prompt  $\Lambda_c^+$  is defined as the followings:

$$R_{\text{AA}}(p_T) = \frac{1}{\langle T_{\text{AA}} \rangle} \frac{dN_{\text{PbPb}}^{\Lambda_c^+}}{dp_T} \bigg/ \frac{d\sigma_{\text{pp}}^{\Lambda_c^+}}{dp_T}. \quad (5.4)$$

The nuclear modification factor  $R_{\text{AA}}$  for prompt  $\Lambda_c^+$  baryons in five centrality classes is shown in Fig. 5.21 as a function of  $p_T$ . The results show that  $\Lambda_c^+$  is suppressed in PbPb collisions in 0–90% and 0–10% centrality classes compared to peripheral collisions.

Figure 5.22 shows the  $\Lambda_c^+/D^0$  production ratio as a function of  $p_T$  for pp collisions and PbPb collisions in the centrality range 0–90 and 0–10%. Figure. 5.22 shows that calculations using a color reconnection model is consistent with our results for the  $\Lambda_c^+/D^0$  production ratio in pp collisions within uncertainty. There is a hint of an enhancement in the  $\Lambda_c^+/D^0$  production ratio in PbPb collisions in the  $p_T$  range of 6–10 GeV/ $c$  compared to pp data, but due to the large systematic uncertainty, no solid conclusion can be drawn. The PbPb measurement in the  $p_T$  range 12.5–30 GeV/ $c$  is consistent with the pp result. This lack of an enhancement may suggest that there is no significant contribution from the coalescence process for  $p_T > 12.5$  GeV/ $c$  in PbPb collisions.

**Figure 5.19.** The  $p_T$ -differential Cross Sections For Prompt  $\Lambda_c^+$  Production In pp Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The Bottom Panel Shows Data/Predictions Ratios.

**Figure 5.20.** The  $p_T$ -differential Cross Sections For Prompt  $\Lambda_c^+$  Production In pp Collisions And The  $T_{AA}$ -scaled Yields For Five Centrality Regions Of PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively.

**Figure 5.21.** The Nuclear Modification Factor  $R_{AA}$  Versus  $p_T$  For Prompt  $\Lambda_c^+$  Production. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The band At Unity Labeled Global Uncertainty Includes The Uncertainties For The Luminosity Of pp Collisions, Number Of MinimumBias Events In PbPb Collisions, And Tracking Efficiency.

**Figure 5.22.** The Ratio Of The Production Cross Sections Of Prompt  $\Lambda_c^+$  To Prompt  $D^0$  Versus  $p_T$  From pp Collisions, As Well As 0–90% And 0–10% Centrality Classes In PbPb Collisions. The Boxes And Error Bars Represent The Systematic And Statistical Uncertainties, Respectively. The 6.8 And 7.4% Normalization Uncertainties In pp And PbPb Collisions, Respectively, Are Not Included In The Boxes Representing The Systematic Uncertainties For Each Data Point. The Open Stars Represent The Predictions Of PYTHIA 8 With Color Reconnection [69]. The Black And Purple Solid Lines Are The pp And PbPb Calculations(0–100% centrality) For Prompt  $\Lambda_c^+$  Over Prompt  $D^0$  Production Ratio From Ref. [47], And The Dashed Line Is The pp Calculation From Ref. [72].

## 6. SUMMARY

The  $p_T$ -differential cross sections of inclusive  $\Lambda_c^+$  (including prompt and nonprompt contributions) and prompt  $\Lambda_c^+$  have been measured with 2015 pp/PbPb and 2017/2018 pp/PbPb at 5.02 TeV with CMS detector. The shape of the inclusive  $\Lambda_c^+$   $p_T$  distribution in pp collisions is well described by the PYTHIA8 event generator. GMVFNS predictions with 3 different fragmentation functions are consistent with 2017 pp prompt data within uncertainties with  $p_T > 8$  GeV/ $c$ , while pp data measurements are systematically above these three predictions when  $p_T < 8$  GeV/ $c$ .

There is a suppression of prompt  $\Lambda_c^+$  observed in centrality class: 0-90% and 0-10% in PbPb collisions. This is consistent with the suppression observed in  $D^0$  meson measurements, which is understood to originate from the strong interaction between the charm quark and the quark-gluon plasma.

The  $\Lambda_c^+/D^0$  production ratios in pp collisions are consistent with a model obtained by adding color reconnection in hadronization to PYTHIA8, and also with a model that includes enhanced contributions from the decay of excited charm baryons. There is a hint of an enhancement of  $\Lambda_c^+/D^0$  production ratio in 6–12.5 GeV/ $c$  in PbPb collisions compared with pp production ratio. The  $\Lambda_c^+/D^0$  production ratios in pp and PbPb collisions for  $p_T = 12.5$ –30 GeV/ $c$  are found to be consistent with each other. This may suggest that the coalescence process does not play a significant role in  $\Lambda_c^+$  baryon production in this  $p_T$  range.

## VITA

Rui Xiao graduated from Shandong University in June 2015 with a Bachelor of Science Degree in Physics. She pursued her graduate study at Purdue University from 2015 to 2021. Rui joined the high energy nuclear physics group under Prof. Wei Xie, as a member of the CMS Collaboration. Rui will graduate from Purdue University with a Ph.D in physics in 2021.
